

**EXCERPTS FROM
PROPOSITION 103 TESTIMONY**

Russ Bingham

10 What is the purpose of your testimony?

11 The purpose of my testimony is to demonstrate how the rate of
12 return resulting from a particular rate may be calculated
13 using the discounted return methodology and how it is used in
14 the ratemaking process. Since I have been vitally involved
15 in the development and application of this methodology, I am
16 here to offer a hands-on perspective of how this is applied
17 in actual practice--to ratemaking and other areas.

18 What general characteristics are embodied in the discounted
19 return methodology?

20 First, the DRM is a total return methodology. Income from
21 both underwriting and investment is included. Second, the DRM

1 utilizes a "benchmark surplus" standard as a base in the
2 calculation of return. Third, the DRM provides a method for
3 calculating return regardless of whether return is calculated
4 on a group, company, or line of business basis. This
5 flexibility is intended to allow for recognition of an
6 insurer's unique business characteristics and mix. Finally,
7 by discounting future receipts/payouts, the DRM calculates
8 return and the various return components in today's dollars.

9 What insurance regulatory objectives does the Discounted
10 Return Methodology achieve?

11 The DRM is consistent with the insurance regulatory objectives
12 of maximizing the protection of policyholder funds, and
13 minimizing the risk of insolvency. It maximizes the
14 protection of policyholder funds by assuming that these funds
15 are invested in risk free Treasuries with maturities matching
16 expected liability payouts. This insures that the funds will
17 be available when needed to pay losses.

18 The DRM minimizes the risk of insolvency by establishing
19 prudent levels of leverage. A minimum, or "benchmark" surplus
20 is established after consideration of the characteristics of
21 the business in question. These characteristics include the
22 effected amount and variability of the financial exposure.
23 In simpler terms, this is derived mainly from the amount and

1 timing of future loss payments and the expected variability
2 in this amount and timing.

3 Lastly, the DRM offers an approach which has sufficient
4 flexibility to respond to real world differences in individual
5 company and business.

6 **Please explain the Discounted Return Methodology.**

7 The DRM methodology is intended to provide a measurement of
8 return from all sources of income pertaining to a specific
9 segment of business, valued at the time the business is
10 written. This measurement of return is typically by
11 individual accident year. The five components of income (or
12 loss) as shown in Exhibit A are: underwriting, investment
13 income on insurance cash flows, investment income on benchmark
14 surplus, investment income on residual surplus and other
15 income.

16 Since most insurance operating expenses (e.g. loss payments)
17 occur in the future, their timing as well as magnitude must
18 be considered in the calculation of income. Discounting to
19 present value recognizes the time value of money and includes
20 this resultant investment income as part of operating income.
21 The principal cash flows considered are premium receipts, loss
22 and expense payments, and prepayment of tax due to both the

1 loss discounting and the 20% unearned premium offset
2 provisions of the new tax law.

3 The paramount importance of meeting policyholder liabilities
4 dictates certain investment principles aimed at reducing risk.
5 Under the DRM, operating cash flows are assumed to be invested
6 only in "risk free" treasury securities and in maturities that
7 match the average duration of liabilities (i.e. average loss
8 payout). This effectively isolates operating income, and
9 therefore policyholders, from investment risk caused by either
10 fluctuating interest rates or market volatility. As a result,
11 prices charged for insurance would not reflect these market
12 risks.

13 Investment in bonds with maturities longer than indicated by
14 loss payouts would expose the principal to an increase in
15 interest rates since the value of bonds would drop
16 accordingly. Investment in bonds with shorter maturities
17 would result in a reduced yield if interest rates were to fall
18 since reinvestment of funds at a lower rate would be required
19 until the payment of the liability.

20 Operating Income is the sum of underwriting income and the
21 investment income derived from policyholder supplied funds
22 invested consistent with these principles, on an after tax
23 basis. Calculation of total rate of return requires that this

1 be measured in relation to some amount of capital, after
2 adding investment income on this capital.

3 Benchmark surplus is that amount of capital that is necessary
4 to enable an insurer to carry on its insurance operations
5 subject to control of the solvency risk. The amount of this
6 benchmark surplus is a function of the characteristics of the
7 insurance exposure to which it relates. This must be
8 determined with due recognition given to both the magnitude
9 and the volatility inherent in the financial exposure in a
10 line of business. Determination of an appropriate benchmark
11 is a complex but necessary task under the DRM.

12 As with operating cash flows, benchmark surplus also is
13 assumed to be invested in risk free treasuries. Less than
14 100% of benchmark surplus is invested, because a portion of
15 the benchmark surplus is invested in the normal overhead such
16 as the plant and equipment required for the insurance
17 operations and which does not produce investment income.

18 Total benchmark return for ratemaking purposes is the sum of
19 income from underwriting, investment income from insurance
20 cash flows, and investment income from benchmark surplus
21 expressed as a percentage of benchmark surplus.

22 It is a total return methodology in that it includes income
23 from policyholder supplied funds, underwriting and the

1 benchmark surplus. Income (or loss) derived from riskier
2 investments and greater (or less) than required surplus is not
3 included at this point in the analysis.

4 The DRM does not use imbedded or portfolio yields for two
5 reasons. First, it lacks the risk free attributes of treasury
6 bonds that I have already mentioned. Second, and equally as
7 important, I believe that it contradicts the fundamental
8 principle of ratemaking which requires that all prospective
9 revenue and expense be considered. We need to know what
10 investment income can be anticipated in the future, not what
11 we have achieved in the past. It is the interest rate on new
12 money that matters.

13 The portfolio imbedded yield is the result of past investment
14 policy and underwriting results. The imbedded yield is, in
15 fact, largely due to the realization of investment income from
16 previous accident year cash flows, especially loss reserves.
17 To use this prospectively is inappropriate. Ratemaking must
18 properly reflect future interest rates.

19 A summary of the methodology is shown in Exhibit B to
20 demonstrate all the required assumptions and the results of
21 this methodology.

1 Please explain how the benchmark surplus concept is related
2 to risk.

3 Two sources of risk inherent to an insurance company are
4 insurance and investment activities. If underwriting cash
5 flows are invested at a "risk free" rate and maturities match
6 liabilities (i.e. loss payouts), operating income will
7 essentially be isolated from the effects of investment policy
8 and market volatility. As a result, insurance risk will be
9 dependent primarily on underwriting. It should be noted that
10 the effectiveness of such an investment policy is affected by
11 the degree to which actual payouts differ from those expected.

12 Investment risk results from the investment policy of the
13 company concerning types of investments and maturities, which
14 gives rise to yield and default risks and related volatility.

15 Solvency risk results from the exposure of surplus to both the
16 insurance and the investment risk. The magnitude and
17 volatility of underwriting losses together with fluctuating
18 investment results are key determinants of this risk.

19 An important aspect of the DRM and management of the solvency
20 risk involves the determination of the proper level of minimum
21 surplus. Surplus is a buffer whose minimum size must be

1 determined through recognition of both the magnitude and
2 volatility of financial exposure inherent in the line of
3 business to which it relates in order to ensure a low
4 probability of insolvency. Surplus should be a function of
5 two factors:

6 1) The degree and magnitude of financial exposure. This
7 essentially is the amount and length of time over which funds
8 are committed to pay the liabilities of a respective line of
9 business.

10 2) The volatility in this funding requirement created by the
11 variability in underwriting and investment. Increased surplus
12 is required to maintain a low probability of insolvency in the
13 face of increased volatility.

14 **How is the appropriate amount of benchmark surplus determined?**

15 Liability funding requirements are determined by line of
16 business to determine the magnitude of financial exposure.
17 The amount of assets that are needed to fund (i.e. to pay) the
18 liabilities for a particular level of business are determined.
19 Specifically, it is the present value equivalent in assets
20 that are required to meet the liabilities inherent in all
21 expected future cash flows. It is based on the magnitude of
22 the cash flows and the length of time that it takes to settle

1 them, discounted to present value.

2 Total funding across all lines of business determines the
3 total invested assets that must be committed by a company to
4 support all writings.

5 Benchmark surplus is set initially for all lines of business
6 in direct proportion to funding requirements (i.e. money at
7 risk). If the timing and magnitude of future operating cash
8 flows were known with a high degree of certainty, only a small
9 amount of surplus would be needed. However, since most
10 insurance cash flows are in the future and are volatile and
11 uncertain, an increased buffer must be established to
12 recognize this fact. The degree of volatility and uncertainty
13 varies among lines of business and the surplus must vary
14 accordingly. In this regard insurance differs substantially
15 from banking and other financial services.

16 While characteristics such as catastrophe and earthquake
17 exposure introduce obvious volatility, the increasing
18 complexity of insurance together with the nature of the
19 prospective costs of providing the insurance also introduces
20 a great deal of financial uncertainty into the process. This
21 must be reflected in the methodology employed to determine a
22 final benchmark surplus.

1 The calculation of funding involves several factors which are
2 subject to variability. The variability associated with these
3 factors is the key to the determination of benchmark surplus.

4 The parameters upon which funding is based include:

- 5 - premium amount and timing of collection
- 6 - expense amount and timing of payment
- 7 - loss amount and timing of payment
- 8 - tax law loss discount factor and timing
- 9 - proportion of premium unearned at year-end
- 10 - market interest rate
- 11 - tax rate

12 The most dominant factors in terms of variability are loss
13 amount and timing of payment. The variability in all other
14 factors, for typical lines of business, has relatively minor
15 effect by comparison.

16 In summary, benchmark surplus is established as a buffer whose
17 minimum size must be determined by recognizing both the
18 magnitude and volatility of financial exposure inherent in the
19 line of business to which it relates in order to ensure a
20 minimal risk of insolvency.

1 How does the benchmark surplus concept compare to the
2 Department's leverage norms?

3 The Department's approach differs from the concept of
4 benchmark surplus in four ways:

5 First, the Department has primarily used the loss reserve
6 liability as the basis for establishing these benchmarks.
7 Under the DRM, the additional liabilities associated with
8 premium collection, expense payment, and tax payment due to
9 loss discounting and the unearned premium offset are also
10 considered. The amount and timing of these liabilities are
11 used to determine a net liability, on a discounted basis.

12 Second, the Department's overly simplified approach gives no
13 consideration to the variability inherent in the insurance
14 business. The calculation of historical ratios of loss
15 reserves to surplus does not recognize the degree to which
16 losses and reserves can vary over time. This most critical
17 aspect has been completely ignored. The leverage ratios set
18 by the Department do not allow companies to reflect their
19 individual risk characteristics. This flexibility is
20 necessary.

21 Third, the long established 2/1 overall leverage level has

1 evolved over the years from experience and judgement of the
2 riskiness of insurance. The NAIC and A.M. Best both
3 implicitly endorse a 2/1 level. Until proven incorrect, this
4 tradition should not be ignored. Any method should, at least
5 as a check, calculate an all lines total for comparison to
6 this figure. The Department's leverage norms clearly fail in
7 this test, averaging approximately 2.5 or more, and an
8 artificially low 1.3 leverage factor in workers' compensation
9 is needed to bring the total down to 2/1.

10 The increasing complexity of insurance and the liberal
11 interpretation of coverage conditions make it ever more
12 difficult to forecast the future. Generally, industry
13 leverage has been declining over recent years, in part
14 reflecting this increased business uncertainty. Concern over
15 solvency should, if anything, support movement below the 2/1
16 norm rather than above it.

17 Finally, the Department's factors are much too crude, having
18 been rounded to whole numbers except in the case of Automobile
19 Liability. There is a major difference in 1/1, 2/1 and 3/1,
20 etc. and the use of such crude norms is not sufficiently
21 sensitive to reflect the true differences among lines of
22 insurance.

23 The Department's approach is so lacking in foundation and

1 substance, that its use could produce distorted results. For
2 this reason, and further since no single set of benchmark
3 leverage norms can apply to each and every company, the
4 Department should use an overall 2/1 ratio as a guide in the
5 review process.

6 How could the Department utilize the benchmark surplus concept
7 in reviewing rates?

8 I would recommend that companies that determine rates on a
9 total return basis by line provide it's own benchmarks
10 calculated based upon its own unique characteristics and
11 utilizing its own ratemaking methodology. These benchmark
12 leverage factors would simply be another input to the
13 ratemaking process, much like loss trends factors and loss
14 development factors that would be subject to review. The
15 average of the benchmark leverage factors should approximate
16 2/1 on an overall basis.

17 For those companies that do not assign a leverage factor by
18 line of business, choosing instead to use a return on premium
19 approach to ratemaking, the Department should use an overall
20 2/1 average as a flexible guideline to convert from total
21 return to return on premium. In no case should an inflexible
22 set of leverage norms or benchmarks be imposed on all
23 companies.

1 Do you believe surplus is divisible?

2 I acknowledge that all surplus of a company ultimately
3 supports every line of business. However, for ratemaking
4 purposes, I believe it is appropriate to assess the
5 risk/return relationship among the lines of business within
6 a multi-line insurance company in much the same way as it is
7 done from industry to industry.

8 The DRM employs benchmark surplus for ratemaking purposes as
9 a method to evaluate and quantify differences in risk by line
10 consistent with a total return methodology.

11 Please explain further how benchmark return differs from a
12 company's actual total return.

13 The benchmark return will differ from actual results in two
14 ways. First, policyholder funds are assumed to be invested
15 in risk free Treasury securities for reasons outlined earlier.
16 Second, a benchmark surplus is established, based on the
17 control of solvency risk. The benchmark return is calculated
18 as the income from underwriting and the investment income from
19 policyholder funds and benchmark surplus divided by the
20 benchmark surplus. The DRM mathematically reflects income
21 from all sources that relate to the basic insurance operation

1 - underwriting, investment income of policyholder funds and
2 supporting surplus.

3 The benchmark return will differ from actual total return,
4 which is based on reported income and surplus. Benchmark
5 return may be either more or less than actual total return.
6 Actual stock market experience and the realization of capital
7 gains, for example, will largely determine whether actual or
8 benchmark returns are greater. In this context, the risks and
9 rewards of investment and capital management policies are
10 borne entirely by the owners of the company and reflected when
11 published in the total company return.

12 Explain how the Discounted Return Methodology is utilized in
13 ratemaking, and how the Discounted Return Methodology relates
14 to a return on premium approach.

15 In ratemaking, a desired benchmark return on surplus is
16 selected first and the premium level is "backed into". This
17 is a short step from the traditional return on premium (ROP)
18 approach which backs into the premium level based solely on
19 a selected ROP. The following benchmark return formula (see
20 Exhibit A) is used.

1 Return on Benchmark Surplus

2 = Return on Premium x Premium to Benchmark Surplus ratio
3 + Investment Rate on Benchmark
4 Surplus

5
$$\text{BROS} = \text{ROP} \times (\text{P/S}) + \text{R}$$

6 A premium to benchmark surplus ratio and investment rate on
7 benchmark surplus are the only additional requirements beyond
8 those assumptions and data bases required for ROP ratemaking.
9 Exhibit C offers an example of how this would work.

10 Application of this methodology simply requires determination
11 of individual company and line of business characteristics
12 regarding the following input assumptions:

- 13 . Expense ratio
- 14 . Investment yield curve (treasuries)
- 15 . Premium, expense, and loss collection and payout patterns
16 (i.e. average payment dates)
- 17 . Benchmark leverage
- 18 . Target benchmark return

19 No opinion is being expressed as to what the fair rate of
20 return should be. The method simply provides a basis for
21 calculation of a premium once this rate of return is provided.

1 **Would you summarize the principle advantages of the discounted**
2 **return methodology?**

3 The DRM satisfies the statutory requirement of reflecting
4 investment income in ratemaking. The DRM offers the greatest
5 protection of policyholder supplied funds by investing in risk
6 free Treasury bonds where maturities match expected payouts.
7 Together with prudent levels of surplus established for each
8 line of business, a total return is calculated in a consistent
9 manner.

10 The DRM offers a sound, practical means for accomplishing many
11 of the Department's objectives, while still maintaining a
12 large degree of flexibility to reflect individual company
13 characteristics.

14 Does this conclude your testimony?

15 Yes.

EXHIBIT A

Sources of Income

- . Underwriting
- . Investment of Insurance Cash Flows
(e.g. Loss Reserves prior to Loss Payment)
- . Investment of Benchmark Surplus
- . Investment of Residual Surplus.
- . Other Income

Formula Summary

Operating Income = Underwriting Income + Investment Income on
Insurance Cash Flows

Return on Premium (ROP) = Operating Income / Premium

Total Benchmark Income = Operating Income + Investment Rate on
Surplus (Rs) x Benchmark Surplus

Return on Benchmark Surplus (BROS) = Total Benchmark Income
/ Benchmark Surplus

BROS = ROP X (P/S) + Rs

Total Income = Total Benchmark Income + Residual Income

Total Return on Total Surplus (TROS) = Total Income / Total Surplus

Notes: All Items are After Tax.

Discounted Return values all items at a single point in time,
usually when the policy is written.

EXHIBIT B : Calculation of Return

Input Assumptions

FINANCIALS	\$	Ratios
Premium	\$100.0	
Loss & Loss Expense	\$83.0	83.0%
Underwriting Expense	\$27.0	27.0%
Combined Loss and All Expense	\$110.0	110.0%

Total Benchmark Return		17.0%

ATTACHMENT 1
GENERAL DEFINITIONS AND FORMULAS

Underwriting Income = (P-E-L) (1-T)

Where P= Premium, E= Expense, L= Loss, T= Tax Rate

Nominal Basis

Operating Return = Underwriting Income
+ Investment Income on Insurance Liabilities

Total Return = Operating Return
+ Investment Income on Surplus

Discounted Basis

Operating Return = Underwriting Income
+ Investment Income Credit on Insurance Float

Investment Income Credit (IIC) = Present value of Investment Income
on All Cash Flows related to
the Accident Period

Premium	IIC	=	$-(1-D_p) P$
Expense	IIC	=	$(1-D_e) E$
Loss	IIC	=	$(1-D_l) L$
UPR Tax	IIC	=	$-(1-D_u) (.2T) P U$
Disc Tax IIC : See Attachment 2 for formula			

Where D = $1/(1+R)^N$ i.e. Discount Factor
R = rate for calculating discount, after tax
Rb = tax law discount rate before tax
N = average payment date for Premium, Expense,
or Loss, respectively
for Du, N = 1, UPR tax recovery payment date
U = Annual Premium year end Unearned factor
(i.e. Unearned Premium/Premium)

Nominal/Discounted Reconciliation

Discounted Operating Return = Nominal Ending Total Return / $(1+R)^N$,

Where N is the ending period when all insurance cash flows have been settled

All dollar figures and discount factors are After Tax except discount factor for Loss Discounting using Rb, the tax law discount rate.

ATTACHMENT 2
LOSS DISCOUNTING INVESTMENT INCOME CREDIT FACTOR
(Factor times Loss for \$ Impact)

1) Actual and Law Rates and Payouts Same

$$- \{ (Db - Da) + T(1 - Db) \}$$

Where $D = 1/(1+R)^N$, i.e. Discount Factor
 $R =$ rate for calculating discount
 $N =$ payment date
 $b =$ before tax
 $a =$ after tax
 $T =$ tax rate
 $Da = 1/(1+Ra)^N$
 $Ra = (1-T)Rb$

2) Actual and Law Rates Different, Payouts Same

$$- \{ (Dr'b - Da) + T(1 - Dr'b) \} \\ + (Dr'b - Da)(Ra - R'a)/(Ra - R'b) \quad (\text{Rate Adjustment})$$

Where $'$ signifies using law rate

3) Actual and Law Rates and Payouts Different

$$- \{ (Dn'r'b - Dn'a) + T(1 - Dn'r'b) \} \\ + (Dn'r'b - Dn'a)(Ra - R'a)/(Ra - R'b) \quad (\text{Rate Adjustment}) \\ + TDa \{ (1 - Dn''r'b) - (Dn''r'b - Dn''a)R'b/(Ra - R'b) \} \\ (\text{Date Adjustment})$$

Where $'$ signifies using law rate or payment date
 $n'' = n' - n$ i.e. difference in payment date

Effect of different Rates is greater than Payout differences and Formula 2) is sufficiently accurate for most applications.

Lower case letters are subscripts and not numeric values.

An approximate formula to the above is

$$- T \{ (1 - Dmra) \times (1 - Dn'r'b) \}, \text{ where } m = (n+1)/2 \\ = - T \{ (1 - 1/(1+Ra)^m) \times (1 - 1/(1+R'b)^n) \}$$
