Discrimination and insurance

Abstract

Is it fair and just to charge men and women identical life insurance premiums despite their different actuarial risk? What about charging the old and the young different premiums? As entities whose core business is to classify people based on their actuarial risk, should private insurance companies not be allowed to discriminate between various groups? To answer these and various other questions, I start this chapter by revealing the complete confusion that exists in the legal terrain with respect to antidiscrimination norms in insurance. I then show how philosophers writing about discrimination mostly have been writing at a level of abstraction so high that it comfortably ignores relevant nuances, thus making the entire literature largely useless for any insurance-related policy-making purposes. I conclude by proposing a theoretical framework that can help policy makers apply a fair and just anti-discrimination policy.
Introduction.

Private insurance is everywhere. As the primary device to reduce risk of loss and uncertainty, insurance is one of the most important institutions around us. It provides financial support in business and human life, it encourages safety and saving behaviors, and it provides security from catastrophic losses as well as peace of mind when aging. Insurance even promotes economic growth and international trade. And yet, very little is known about the requirements of justice and specifically of equality and fair non-discrimination norms from private insurance providers. As entities that offer services to the public, are they subject to the same norms as public entities? As entities whose core business is to classify people based on their actuarial risk, are they not allowed to discriminate between various groups?

Indeed, what is unique about insurance is that even statistical discrimination (the act by which an insurer uses a characteristic of an insured or potential insured as a statistic for the risk it poses to an insurer), which by definition is absent any malicious intentions, poses significant moral and legal challenges. Why? Because on the one hand, policy makers would like insurers to treat their insureds equally, without discriminating based on race, gender, age, or other characteristics, even if it makes statistical sense to discriminate. Indeed, the US Supreme Court has expressed this aim of policy makers regarding insurance: "[e]ven a true generalization about [a] class cannot justify class-based treatment" (Norris 1983). On the other hand, at the core of insurance business lies discrimination between risky and non-risky insureds. But riskiness often statistically correlates with the same characteristics policy makers would like to prohibit insurers from taking into account. In fact, historically, courts in the EU and the US have permitted insurers to account for these characteristics; some because such a practice is required to maintain healthy insurance
markets, and others because in their view the practice (in the absence of malicious intentions) is a *manifestation* of the equality principle. As one American court wrote: “[r]isk discrimination is not race discrimination” (*Nat’l Assoc. For The Advancement Of Colored People*, 1992).

The picture is further complicated by the fact that insurance is both a social and a private enterprise. While social, government-provided insurance reflects ideals of solidarity and cross-subsidization of risk among the citizens, private insurance is profit-driven, thus requiring different risk pricing. But even private insurance requires a license from the state and states often require their citizens to purchase various types of insurance. The protection from competition and the guaranteed demand for their products can justify imposing antidiscrimination norms on private actors. Indeed, states have struggled to find a middle ground between complete prohibition and complete permission, by prohibiting risk differentiation if it amounts to “unfair discrimination.” The problem, however, remained because “unfair discrimination” remained undefined. Indeed, states' constitutions and the main human rights documents only provide a list of prohibited grounds for discrimination, without ever defining discrimination.

The goal of this chapter is to try to reimagine private insurance as an institution complying with the fundamental requirements of justice, and specifically with fairness and non-discrimination norms. My first goal is to highlight the unique features required for the understanding of the seeming oxymoron *fair* discrimination in insurance. My second goal is to introduce a nuanced way to understand how costs matter in the determination of whether insurance discrimination is overall *just*. (I use the word “fair” for the deontological, cost-blind requirement to not discriminate, as
discrimination is prima facie wrong, and the word “just” for the consequentialist, costs-conscious requirement to not wrongfully discriminate, all things -including costs - considered.)

Given the scope here, I do not attempt to develop an original and robust account of the wrongfulness of discrimination, which would capture all our intuitions and be resistant to all philosophical objections. Others have already brilliantly failed at this undertaking before. Instead, I draw on other philosophers’ work on discrimination, most of which is not directly on insurance, in order to extract insights relevant to fair insurance practice. Then, because I believe that justice cannot be blind to costs, I also build on the literature on the social costs of prohibition on discrimination in insurance markets in my attempt to draw a skeleton for a theoretical framework for a just discrimination in insurance. Ultimately, I argue that there is no one-size-fits-all answer to the questions of what a fair and just insurance policy is. Rather, the answer varies from one line of insurance to another and from one characteristic to another, as well as from one type of discriminatory treatment to another. To illustrate this point, consider the following two examples:

**Example 1:** In a landmark case in 2011, the European Court of Justice entirely forbade charging women less than men for their life insurance, even though on average, women live longer than men and therefore are less likely to die in any given year (*Test-Achats 2011*). By contrast, this practice is not entirely forbidden in many US states.

**Example 2:** In a couple of landmark cases in late 1970s and early 1980s, the US Supreme Court entirely forbade charging women more than men for their employer-provided pension insurance funds or providing them with smaller monthly benefits, even though on average, women live longer than men and therefore require pension benefits for a longer...
period of time (Manhart 1978, Norris 1983). By contrast, this practice is not entirely
forbidden in the EU.

Which approach does equality support? What can and should explain the differences between the
EU and US? Besides the cross-continental difference, an internal inconsistency exists as well. Life
insurance provides coverage for dying too early, whereas pension insurance provides coverage for
dying too late, so to speak. It seems that norms of antidiscrimination should have the same impact
in both types of insurance; yet each legal system reverses its own treatment of gender
discrimination between pension insurance and life insurance.

The puzzle is not limited to any one line of insurance or insurer characteristic; rather, it pervades
the entire institution. It might be obvious that people should not be denied insurance or charged a
higher premium because of their race, but what about people who are overweight (cf. chapters 16
and 22)? Is this class protected? And even if it is protected, is it protected no matter what the costs
to the rest of the pool or society are?

**The Existing Approach for Statistical Discrimination by Insurers**

With some notable exceptions, in most of the cases both the EU and the US require insurers to
balance equality and efficient business practices by refraining from “unfair discrimination.”
However, how they should strike that balance remains a normative mystery. Below, I scan the
legal landscape in both the EU and the US. My goal is to expose in more detail the inconsistency
already revealed in the examples above. It remains an open question whether this inconsistency
reflects substantive disagreements about moral first principles, about the proper implementation
of (otherwise consensual) first principles, or about second-order considerations such as market conditions or path dependency. This question can only be answered once philosophers provide a robust theoretical framework for unfair discrimination in insurance and economists provide evidence about the social cost of the prohibition on unfair discrimination.

The EU Legal Landscape

Article 5(1) of Council Directive 2004/113/EC of 13 December 2004 implemented the principle of equal treatment between men and women in the access to and supply of goods and services. It provides that “the use of sex as an actuarial factor in the calculation of premiums and benefits must not result in differences in individuals’ premiums and benefits.” Article 5(2), however, allowed deviation from the prohibition if the use of sex is “based on relevant and accurate actuarial and statistical data.” In the above mentioned landmark case (the 2011 Test-Achats ruling), the Court of Justice of the European Union declared article 5(2) invalid, meaning that gender can no longer be taken into account, even if makes actuarial sense.

Despite its seeming applicability to all lines of insurance, the Test-Achats ruling did not create a reliable bright line. As the European Commission has subsequently clarified, it remains possible for insurers to offer gender-specific insurance products to cover gender-specific conditions such as prostate cancer or breast cancer. On the other hand, and to further complicate matters, this option is prohibited when it comes to pregnancy and maternity, in light of the specific solidarity mechanism created by Article 5(3). But that is not all. The line continues to blur because the use of risk factors that might be correlated with gender remains permissible as long as they comprise real risk factors in their own right. For example, in the field of auto insurance, price differentiation
based on the size of a car engine is acceptable, even if statistically, men drive cars with engines that are more powerful. In other words, while direct statistical discrimination was prohibited, indirect statistical discrimination was not (cf. chapters 1 and 2).

Certain other inconsistencies remain in the wake of the Test-Achats ruling. For example, Article 9[1][h] of Directive 2006/54/EC, which applies to pension plans, allows for the setting of different levels of benefits between males and females when justified by actuarial factors. One would expect that because pension and life insurance cover similar risk (the risk of not knowing when one would die) the Test-Achats ruling will apply to pension plans as well. And yet, according to the European Commission, Test-Achats has no impact on this provision. Lastly, the European Commission also explained that the Test-Achats ruling does not affect the use of other in many ways similar risk-rating factors, such as age or disability.

The US Legal Landscape

In the US, the situation is somewhat different, though equally inconsistent. To date, most states in the US have adopted some form of a baseline prohibition against “unfair discrimination between individuals of the same class and essentially the same hazard.” Typically, this prohibition does not apply: “where the refusal, limitation, or rate differential is based on sound actuarial principles or is related to actual or reasonably anticipated experience.” (See e.g. NY Code - Section 4224). What are those “sound actuarial principles” or “reasonably anticipated experience[s]” that justify discrimination? No one really knows. Indeed, a great deal of inconsistency exists in the treatment of anti-discrimination norms in the U.S. This inconsistency exists in federal laws and state laws,
across coverage lines and policyholder characteristics, and in both the substance and the intensity of regulation.

*Inconsistent Treatment of Discrimination across States’ Statutes.* In the US, insurance law is primarily governed by the states, not the federal government. The variation of the specific laws governing discrimination practices exists not only across states, but also internally, across lines of insurance and policyholder characteristics. Whereas Montana flatly forbids gender discrimination, California requires it—comprising an example of *cross-state variation* (Avraham et al. 2014). State regulation of discrimination in the automobile and property lines of insurance is more robust than in the cases of health, life, or disability insurance—comprising *cross-line variations*. One particular example of cross-line variation is that many states prohibited insurers’ use of genetic information in health insurance. However, states hardly regulate the use of such information for other lines of insurance, including life or disability insurance where genetic information matters. An example of a *cross-characteristics variation* is that before Obamacare, insurers were allowed to use gender in health insurance underwriting decisions, but were not allowed to use race for the same purpose. The *cross-state, cross-line, and cross-characteristics* variations of states’ specific laws remain normatively unexplained (but see Avraham et al. 2015).

*Inconsistent Treatment of Discrimination by Courts.* The inconsistent treatment of discrimination by states’ legislatures is further reflected in courts’ interpretation of the statutory term, “unfair discrimination.” In the context of auto insurance, for example, courts found that automobile insurance rates based upon sex and age are fair unless those sex-and-age-based rating factors are found to be actuarially unsound.³ Yet, other courts have forbidden auto insurers from
discriminating based on age, sex, or zip code. A similar dynamic exists with respect to race. Some courts permitted life insurers or homeowner insurers to charge African Americans higher premiums than Caucasians since the difference was based on statistical risk, while other courts prohibited such practices.

Inconsistent Treatment of Discrimination by Legal Commentators. The vast majority of legal and philosophy scholars writing on discrimination did not write about it in the context of insurance; the vast majority of scholars writing on insurance have not considered questions of discrimination. An important exception happened in the US around the years when the Supreme Court delivered the aforementioned cases of Norris and Manhart decisions, when a lively debate on the permissibility of gender discrimination in pension insurance emerged between lawyers and economists. Some scholars argue that actuarial fairness is fair (Gerber 1975; Kimball 1979; Benston 1982; Bailey et al. 1976) or can be made fair (Gaulding 1995; Wortham 1985). Other scholars consider “rational” discrimination to be repugnant (Sydlaske 1975; Laycock and Sullivan 1981; Brilmayer et al. 1984).

Interestingly, neither camp can justify the tremendous variation that exists in the law. For example, neither camp can explain why race discrimination is considered repugnant, while gender discrimination is so often deemed acceptable in the insurance context. Commentators on both sides of the debate have noted this inconsistency and have argued that the laws should be changed to eliminate it where one camp argues that both race and sex discrimination should be allowed because both race and sex are statistically correlated with risk, whereas the other camp, by contrast, argues that neither form of discrimination should be allowed because both race and sex are
categories over which individuals have no control or are historically invidious classifiers, or because using such classifications perpetuates undesirable stereotypes about race and gender—or some combination of these arguments.

With a few important exceptions (Wortham 1986; Gaulding 1985), commentary has focused on whether particular classifications should be forbidden from an antidiscrimination perspective. The commentary usually focuses on one or two insurance lines, such as life insurance and pensions (Brilmayer et al. 1984; Hoffman 2003). Developing a general normative framework, however, comprises a different challenge, requiring legal, economic, and philosophical foundations in order to determine the appropriate contours of discrimination in the entire universe of insurance. Such an undertaking also requires empirical investigation to account for the costs of implementing those norms in light of the market conditions. I now turn to highlighting the unique features of insurance that require philosophers to think deeper about what unfair discrimination is in the insurance context.

**Unique Features of a Theoretical Framework**

For egalitarians, "fair" practices means "just" or "equal" practices, meaning that insurers should drop from their analysis and calculations any characteristics whose use is normatively repugnant, such as race or gender. For actuaries and economists, "fair" practices means "actuarially fair," which also means "efficient." Accordingly, each insured pays a premium that reflects his or her risk. Risk is proxied by any classifier that substantially correlates with risk, including race and gender, even when the particular classification characterizes socially salient groups that might deserve constitutional protection. Proponents of this approach thus believe that the use of such
proxies surmounts to rational actuarial discrimination; namely, permissible discrimination founded in business necessity (cf. chapter 3). So how should we reconcile the competing anti-discrimination norms and fundamental insurance practices?

Philosophers seem to agree that any conception of unfair discrimination must include some disadvantageous (and not merely differential) treatment of people based on their perceived membership in a socially salient group. However, philosophers disagree on what such discrimination exactly means and what makes it unfair. In recent insurance practices the issue is complicated further as insurers usually no longer intentionally attempt to disadvantage insureds for belonging to a certain group (the so-called disparate treatment), but rather evaluate in good faith insureds' individual risk based on the readily available statistical data for that group (for the so-called disparate impact). In short, discrimination in insurance no longer deals with the problem of intentional discrimination, but rather with the problem of statistical discrimination. Moreover, even the limited discussion of statistical discrimination that exists deals with direct statistical discrimination and almost completely ignores the hard problem of indirect statistical discrimination, such as when insurers discriminate based on a characteristic (such as the size of the car engine) that correlates with a protected class (such as gender).

Moreau’s view is that discrimination is wrong because it violates our deliberative freedoms, which are our “freedoms to have our decisions about how to live insulated from the effects of normatively extraneous features of us, such as our skin color or gender” (Moreau 2010 pp147; chapter 13). It is unclear, however, whether Moreau would consider actuary risks, such as different mortality risks men and women face, as normatively extraneous features. Another view is that discrimination
is wrong when it treats people disadvantageously based on immutable traits (Kahlenberg 1996; cf. chapter 18). Sometimes, however, protection from discrimination is given even to mutable traits such as religion, while in other instances protection from discrimination is not given to immutable traits, such as denying blind people car insurance (Boxill 1992). Dworkin has argued that discriminatory acts are those that could be justified only if a certain prejudiced belief were correct. The absence of a “prejudice-free justification” thus makes a law or policy discriminatory (Dworkin 1985). Suppose, however, that there are bad ways of treating women that are unjustifiable no matter which prejudiced beliefs may be true, such as preventing women from undertaking physical jobs because on average they are shorter than men. Surely, treating women in that way while treating men much better could be discriminatory even though the stereotype might be correct. Indeed, Fred Schauer has argued that discrimination is wrong even when it relies on somewhat accurate stereotypes, which may apply to many but not all members of the group (Schauer 2003). A related view is that discrimination is wrong because it fails to treat people based on their individual merit (Hook 1995). The problem with this approach, however, is that it cannot explain what is distinctively wrong about failing to treat people based on merit (Cavanagh 2002). Does any disrespectful treatment of members of disadvantaged group constitute discrimination?

Hellman holds that direct discrimination is wrong because it demeans those against whom it is directed, treating them as morally inferior rather than morally equal (Hellman 2008; chapter 7). A related view argues that people are entitled to as much respect or concern as the dominant group not merely from the state but also in their daily relationships with other individuals or corporations (cf. chapters 6 and 35). To be in a “just relationship” with others, participants must interact with each other in a way that respects the individuality of each (Dagan and Dorfman 2015). Of course,
what counts as *demeaning* and what the idea of "just relationship" requires in the context of insurance remains to be worked out. Is charging women a lower life insurance premium demeaning? What about charging a higher pension contribution? Lippert-Rasmussen disagrees with the broad school of thought under which Hellman’s approach falls, which he calls “[t]he disrespect-based account of the badness of discrimination” (Lippert-Rasmussen 2013). Lippert-Rasmussen argues that discrimination is wrong primarily because of its harmful effects (cf. chapter 12). But harmful compared to what? His view is that it should be harmful compared to the counterfactual situation whereby such discrimination does not exist. But what if prohibition on discrimination harms the disadvantaged group in the short run, yet advantages it in the long run? Scholars have argued that the EU’s recent prohibition on gender discrimination in insurance raised premiums for both genders, allegedly making them both worse off. But what if such a prohibition would benefit women in the long run? Lippert-Rasmussen’s approach seems to enable such a forward-looking costs and benefits analysis.

Obviously, in this chapter I cannot fully discuss all or even the few previously noted conceptions of discrimination. Still, my reading of the philosophical literature leaves me with the impression that very rarely does it apply neatly to insurance, where factors such as the relevant line of insurance, the characteristic, as well as the type of discrimination, are extremely important for the determination of what fair discrimination really is. For example, charging the elderly a higher premium for life insurance based on their higher actuarial risk is probably not as bad, if it is bad at all, as completely refusing to sell life insurance to old people, which in turn is probably also not as bad, if it is bad at all, as refusing to sell life insurance to black people even if their actuary risk is as high as that of the elderly. Nor is refusing to sell the elderly life insurance as bad as refusing
to sell the elderly health insurance. But most of the approaches noted above do not seem to advance the conceptualization much in these nuanced contexts.

Moreover, most of the previous conceptions do not place adequate emphasis on costs. But costs also matter. If forbidding discrimination will unravel an entire insurance market or kill hundreds of people a year because bad drivers no longer take caution on the roads because they are insured, policy makers need to pause before they require such insurance practices.

**The Moral Requirements From a Theoretical Framework**

To start filling in the gaps in the existing literature, in what follows I offer a two-stage process policy makers must undertake in order to determine what a *fair* and *just* insurance regime is. I provide a pragmatic sketch of how a more nuanced analysis can help determine whether a specific regime is *fair*. I then show how costs need to be integrated in order to determine whether a specific regime is also *just*.

At the first stage, policy makers must determine whether specific discrimination is *fair*; namely, that it is not prima facie wrong. The answer to this deontological question depends on at least three factors: the characteristic in question, the line of insurance, and the nature of the discriminatory treatment. Once one concludes that some specific insurance practice is *fair* (or unfair), the second stage becomes relevant. In the second stage, one examines whether a specific discrimination (whether fair or unfair) is also *just*, as the social costs of allowing or prohibiting discrimination are taken into account. Such costs might come in three forms: First, a higher premium to the same group the prohibition on discrimination purported to protect; second,
potentially in the form of what economists call adverse selection, or third, even worse, in the form of adverse primary behavior. In other words, whereas the first stage examines the deontological fairness-related commitments private insurers have to their customers, the second stage engages in the tradeoff between equality and its consequences. I now describe these two stages in more detail.

Stage One: The Relevant Factors for Fair Discrimination

A. The First Factor: The Characteristics

Not all characteristics are the same. Both race and age are immutable, and yet in life insurance, we accept age discrimination but usually do not accept discrimination for race (cf. chapters 16 and 20). Indeed, the literature highlights several features that are relevant for the analysis, which is why the analysis is so complicated. First, we must determine whether a characteristic is controllable or immutable. There is some intuitive appeal to prohibiting discrimination that is based on immutable traits, as one should not be disadvantaged for things one has no control over. Indeed, people tend to tolerate discrimination more when choice is perceived to be involved, such as in the contexts of sexual orientation, obesity, and parenthood (Kricheli-Katz 2014). Of course, that does not mean that choice must be a factor, from a normative perspective. Indeed, as the previous example shows, not all immutable characteristics are treated the same. In fact, for discrimination to be wrong, mutability is probably neither a necessary condition (i.e., religion is mutable yet a protected trait) nor a sufficient condition (i.e., blind people are prevented from driving).
The second relevant feature for the analysis is whether the characteristic changes over one’s lifetime (such as age) or stays fixed (Lipert-Rasmussen 2013). It is possible that age discrimination is more tolerable because we all get the same chance to be on the winning side and the losing side of it over the course of our lifetime. Third, we must determine whether a characteristic constitutes a cause of the risk, rather than merely correlating with it (Zarsky 200?). Legal commentators usually demand a causal relationship between the classifier and the risk for the classifier to be taken into account, whereas actuaries often believe that correlation is sufficient. Fourth, the characteristics’ predictive value (of the underlying risk) must be considered; that is, to what extent is the characteristic a good predictor for the risk? The better predictor of risk the characteristic is, the more tolerable such discrimination becomes (cf. chapter 3). Fifth, we should determine whether discrimination on the basis of the characteristic perpetuates negative stereotypes, or otherwise subordinates disadvantaged groups (Hasnas 2002). Sixth, the historical use of the characteristic as a method of discrimination is relevant; that is, whether the characteristic defies a socially salient group that has been disadvantaged in the past. In that sense, discriminating based on skin color is more problematic than based on eye color. Whether a characteristic is socially suspect, of course, is context-dependent. For example, religion might be a more sensitive category in Catholic countries such as Italy, whereas race might be more sensitive in the US. In this context, it is interesting to reflect on the normative classification of ‘new’ socially-suspect classes such as the obese, HIV-positive individuals, or parents.

B. The Second Factor: The Line of Insurance

The importance of each insurance line varies. By importance, I refer to the importance of the insurance to the insured’s autonomy and participation in the polity. For example, health insurance
is more determinative of citizens’ ability to participate in the polity than are some other forms of insurance, such as traveler’s insurance. When considering the disparate importance of these two lines of insurance to society at large, arguments for or against discrimination in the healthcare context have greater moral, economic, (and constitutional) implications than those in the context of traveler’s insurance. While health insurance is more like a social good, or what Rawls called a “primary good,” and many other will consider a basic human right, traveler’s insurance is more like an economic commodity. If a good is an economic commodity, no moral duty necessarily exists to ensure equitable access. But where do life insurance or disability insurance, for example, fall on this spectrum? And what about homeowner’s insurance, car insurance, or mortgage insurance?

C. The Third Factor: The Nature of the Discriminatory Treatment

Insurance companies might discriminate against insureds or potential insureds in various ways. I focus here on discrimination in the underwriting process, and not in the coverage decisions they make after an occurrence. The harshest type of discrimination is to never issue a policy because of some characteristic, such as a blanket refusal to insure blacks. A somewhat similar type of discrimination happens when insurers refuse to renew or when they cancel policies based on some characteristic. Indeed, many states have statutes that limit and others have statutes that prohibit the use of a particular characteristic in either issuance, renewal, or cancellation. Another form of discrimination involves restricting coverage in ways that might harm disadvantaged groups. For example, insurance companies might limit disability coverage to disabilities that do not stem from having HIV. But even with statutes limiting such discrimination, insurance companies can still discriminate against their insureds by simply charging a higher premium. Indeed, some states have
statutes that limit but do not completely prohibit the use of a particular characteristic in rate-setting. Other states have statutes that expressly prohibit insurers from taking into account a specific characteristic, even in setting rates. These discrepancies call for a more nuanced fairness-based analysis of discrimination in insurance. For example, it is possible that fairness requires insurance companies to admit people with various diseases and disabilities to their pool, and yet fairness might still allow insurers to charge these people a higher premium.

The philosophical literature does not provide a nuanced analysis of the three factors described above as applied to insurance. Indeed, this literature rarely expressly relates to insurance at all, as rarely can its general insights directly be applied to insurance. Resultantly, and as we just saw, crucial legal nuances such as the nature of the insured's characteristics, the specific line of insurance, and the exact nature of discrimination remain unanalyzed. In what follows, I focus on another issue that the literature on discrimination overlooks: the role of costs in the analysis.

*Stage Two: The Tradeoff between Equality and its Consequences*

Whether discrimination is just overall, even when it is not fair, depends on the social costs involved. Therefore, policy makers should attempt to account for the actual cost related to discrimination. In this context, three types of costs must be considered. The first is the impact of the prohibition on discrimination on the disadvantaged group it purports to help. For example, imagine a prohibition on a comprehensive auto insurance policy providing *free* roadside assistance to women (but not to men). Such a prohibition can be justified in Stage 1 as fair on the ground that the policy demeans women (Hellman 2008; chapter 7) because it assumes they cannot or do not want to change a flat tire themselves, thus perpetuating a stereotype that women are physically
weaker, are deterred from physical tasks, or cannot handle a car—stereotypes that might hurt them in other markets such as the employment one. (Of course, a policy of free roadside assistance to women might be deemed fair in Stage 1 on the ground that society should be able to entertain the thought that women on average are less good than men at car maintenance and at the same time that women are morally equals to men. But let us assume for now that a Stage 1 analysis determined the policy to be unfair and therefore upheld the prohibition).

Such a prohibition, however, might increase the premium to women, potentially causing some of them—the poorer ones—not to buy comprehensive coverage, thus making them worse off. Oxera (2011) found that after the Test Achats case, which required insurance companies in the EU to have unisex premiums, life insurance premiums increased for women. Similarly, Aseervatham and colleagues (2014) found that following the Test Achats case auto insurance premium increased for young females. Is it self-evident that a policy that boosts fairness (Stage 1) but harms the very same group it purported to help is just? Does the magnitude of the harm to that group not matter?

Policy makers should also consider a second type of losses—efficiency losses in the insurance markets stemming from the fact that due to prohibition on discrimination, one group cross-subsidizes another, which might lead to a problem known to economists as adverse selection. If the insurer prices both races equally, all else being the same, blacks, for example, might pay less than the risk they pose. Insurers fear that certain whites cross-subsidizing blacks will drop out of the insurance pool. The absence of those less risky people will then raise the average riskiness of the pool, raising the cost of premiums for the entire pool and reducing the net benefit that participating in the insurance pool provides to the remaining members of both races. This situation
in and of itself is an efficiency loss. But that might not be all. The reduction in the net benefit might further lead to whites that were previously on the cusp of dropping their participation in the pool to reconsider, causing them to leave the pool as well. Insurers argue that these events happening repeatedly comprise a chain reaction they call a death spiral, which might not end until the entire insurance pool unravels. A similar phenomenon can occur if insurers are banned from using genetic information. People who know they have defective genes will opt into the pool, driving out people without such genes. The end result might be that in the name of equality for everyone, we provide insurance to no one.

Another possibility is that a prohibition on discrimination might lead insurers to conduct a more detailed investigation of each applicant, and that in turn will raise premiums for everyone, dropping the poorer would-be insureds outside of the pool. The outcome would be that equality between the races comes at the expense of the poor of both races. The bottom line is this: can one seriously argue that costs associated with adverse selection never matter for the normative analysis?

Notably, while higher adverse selection costs and costs associated with death spirals are theories well accepted by economists, the empirical evidence of the extent to which they accurately describe the real world is mixed. Cutler and Reber (1998) conducted a detailed analysis of health insurance plans. They show that when Harvard University increased the premium of the most generous health plans for its policyholders regardless of the risk they imposed, the best risks in the pool (the ones with lower medical expenses) left this plan for a less generous one with a lower premium. Other evidence for adverse selection in health insurance markets exist (Cutler
and Zeckhauser (2000). However, in line with my claim in this chapter, in surveying the literature Cohen and Siegleman (2010) found that the significance of the adverse selection effect may vary by line of insurance, the characteristic discriminated against, and the nature of the discrimination. The upshot from all this is that in this regard as well, the analysis must be specific and cannot remain at the general level at which the literature in philosophy comfortably remains.

The third type of costs policy makers need to incorporate is the impact of allowing and prohibiting discrimination on insureds’ primary behavior. Let us start with impact of allowing discrimination. Suppose we conclude in Stage one that discriminating on the basis of genetics is fair, for example because it is not conceptually different from discrimination based on health conditions, which was allowed in the U.S. until Obamacare. Our support of such discrimination may increase once we do our stage-two analysis and consider the risk of adverse selection discussed above. And yet, we must also consider the impact of such policy on insureds’ primary behavior. In our case, if insurers were allowed to discriminate based on clients’ genetics, people might be deterred from having genetic tests. This, in turn, might prevent them from getting preemptive help, as well as prevent society from improving the science of genetic diseases (Hellman 2003). These costs might justify prohibiting genetic discrimination, at least in lines of insurance where people might be deterred from taking the tests, despite such discrimination being fair and despite the costs associated with the risk of adverse selection.

A similar analysis can be conducted for the case when discrimination is prohibited. Let us assume that in the first stage, one concludes that credit score discrimination (which scholars believe to be
an alternative insurance companies found to race discrimination, once the latter was prohibited) should be prohibited in auto insurance. Still, policy makers should be hesitant to forbid credit score discrimination before they understand the empirical picture. In states that prohibit such discrimination in auto insurance, premiums may be lower for drivers with a low credit score. But if low credit score is correlated with substance abuse, such a policy might cause more risky drivers to drive, potentially decreasing overall safety. Is it not crucial to know whether car accident rates rise? What about the number of fatalities and severe injuries? Avraham, Cohen and Shurtz (2016) found that states that prohibited discrimination based on credit score faced an increase of about 3% in fatalities. This extrapolates to about one thousand fatalities a year nationwide. One must pause here and reflect on whether the prohibition on credit discrimination is at all just.

To be sure, it might still be the case that a prohibition on credit score discrimination is not only *fair* (stage one) but also *just*, even once the costs in terms of lost human lives are taken into account (stage two). My point, however, is that the impact on primary behavior involves important empirical questions that policy makers should not ignore.

More generally, I argued in this section that for pragmatic reasons a two-stage analysis is desirable. In the first stage, policy makers should focus on the deontological requirements a fair insurance regime necessitates. My main point there was that a more nuanced analysis, one that takes into account the specific characteristic, the specific line of insurance, and the specific nature of discrimination, is required. In the second stage, policy makers should focus on the costs associated with a fair anti-discrimination regime in order to determine whether it is also just. My main point there was again that a nuanced analysis is extremely important: one that takes into account the
impact on the protected groups' welfare, the impact on insurance markets, and the impact on the primary behavior.

Conclusion

In this chapter, I sketched a contemporary mapping of antidiscrimination insurance laws (statutes, courts decisions, and directives) in both the EU and the US. Of course, inconsistency in legal treatment across and within jurisdictions is rampant in countless areas. Here, I conjectured that the complete legal mess might imply that policy makers still lack the necessary nuanced normative framework regarding optimal insurance anti-discrimination policy. I attempted to start filling in this gap with my two-stage analysis hereby offered.

One question left unanswered is why private insurance companies need to be subject to norms, such as anti-discrimination norm, usually applicable to the government. We never think about asking a grocery store to sell milk or bread to minorities below its costs, and yet we do ask insurance companies to do so when pricing policies. The answer might be that modern life makes insurance companies so large, in terms of their political, economic, and legal influence, that the same rationales originally applied to the relationship between citizens and governments are also relevant to citizens and insurance companies. Insurance companies sell services and spread risks across millions of people, thus serving a large chunk of the polity. Insurance companies are often protected from competition, especially from abroad, thanks to government regulation. Governments routinely mandate and encourage their citizens to buy coverage—a benefit no other private industry enjoys. Insurance companies manage trillions of our dollars, for example our pension funds, which comprise a large proportion of the public’s wealth. Insurance companies are
often too big to fail, which grants them important influence with governments. And yet, it is not entirely clear that costs of equality should not be spread across all citizens rather than just the insurance company’s customers. For example, if a minority neighborhood suffers from a high crime rate due to the government’s neglect, which would naturally result in higher property insurance premiums in that neighborhood, it is not clear that insurance companies (and their customers) should bear the costs for such neglect by being prohibited from charging higher premiums in that neighborhood. Rather, perhaps a sounder regime will be one where the government reimburses insurers for the various costs associated with requiring them to charge an equal premium. This example highlights possible interesting intersections between markets, anti-discrimination norms, and mechanisms of distributive justice. However, adequately addressing these issues lies well beyond the scope of this chapter.

Regulation in Microinsurance Markets:
Principles, Practice, and Directions for Future Development

Christian Biener, Martin Eling, Joan T. Schmit*

Abstract
Regulation of any market can either promote or impede its development, thus affecting social welfare. In this paper, we are concerned with the impact of regulation in microinsurance markets. We evaluate existing and potential regulatory mechanisms with regard to its underlying economic rationale, and offer recommendations intended to enhance support and minimize barriers for microinsurance market development. Specifically, we recommend avoiding incentives for regulatory arbitrage; responding to the characteristics of the microinsurance market, including licensing, capital, reinsurance, and distribution systems; enhancing the market through financial literacy initiatives; and providing support in the form of data collection and management training.

Keywords: Developing countries, microinsurance, regulation

Joan T. Schmit (jschmit@bus.wisc.edu) is with the Department of Actuarial Science, Risk Management & Insurance at the School of Business of the University of Wisconsin–Madison, 5194 Grainger Hall, 975 University Avenue, Madison, WI, 53706, U.S.
1 INTRODUCTION

The global microinsurance industry has grown tremendously over the past few years. The estimated number of policies sold more than tripled between 2009 and 2012, increasing from 135 million to 500 million (see ILO, 2012). Yet, estimates of the underserved market run as high as 4 billion people at the “base of the pyramid” (see World Resources Institute, 2007). A variety of initiatives and organizations have been created to expand insurance penetration in low-income populations; and while these efforts have shown some success, there is still much room for improvement. Among the relevant areas to consider is regulation, which is viewed as having both positive and negative influences on the market. Some countries have passed specific regulation that applies solely to the microinsurance market, and others are considering this option. Furthermore, policymakers have raised the possibility of involving insurance regulators in the promotion of coverage for low-income populations, a role that could go beyond the traditional pricing, solvency, and market conduct functions. Examples include activities to assist insurers with data collection and employee training, as well as initiatives to improve financial literacy and risk management.

We seek to contribute to the discussion by (1) reviewing existing evidence of insurance regulation’s successes and failures in conventional markets, (2) applying those lessons to the microinsurance environment, and (3) identifying situations when regulation may be able to improve microinsurance market conditions, as well as those where it may have deleterious effects. We also discuss several existing microinsurance regulatory schemes to illustrate the current practice.

A successful microinsurance regulatory scheme will promote market development and enhance social welfare. Based on this fundamental idea, we formulate specific recommendations as enumerated in Table 1 and presented in the following sections. Our intention is to support the successful design of future microinsurance regulations.  

Table 1. Recommendations for Microinsurance Regulation

<table>
<thead>
<tr>
<th>Recommendation</th>
<th>Examples</th>
</tr>
</thead>
</table>
| 1. Reduce market entry barriers | ▪ Reconsider licensing requirements, particularly in light of innovative uses of technology and partnerships for product distribution  
▪ Employ risk-based capital requirements  
▪ Define microinsurance in a way that minimizes incentives for regulatory arbitrage  
▪ Recognize the need for higher returns on lower-priced and often riskier products |
| 2. Encourage market demand | ▪ Provide and support comprehensive risk management educational initiatives, including insurance literacy  
▪ Encourage and make available effective risk mitigation strategies  
▪ Enhance underlying services, such as health care  
▪ Enforce regulations and demonstrate intolerance for corruption and fraud |
| 3. Encourage market efficiency | ▪ Offer data and management support  
▪ Provide training to agents, actuaries, underwriters, and insurance managers  
▪ Allow and encourage involvement of international reinsurers and alternative risk transfer mechanisms |

The remainder of this paper is structured as follows. In Section 2 we review the general rationale for insurance regulation, develop criteria for successful insurance regulation based on economic theory, and review the literature regarding microinsurance regulation. In Section 3 we present characteristics of the microinsurance market that have direct implications for regulation. Among these are product and market conditions distinct from the conventional market; the acute need for administrative efficiency because of the low premium value per policy; the need for improved financial literacy as well as underlying services covered by insurance; and the role of informal support mechanisms. We discuss and describe current specific microinsurance regulatory schemes in Section 4, and conclude in Section 5.

2 RATIONALE FOR INSURANCE REGULATION

(a) General

Insurance regulation has been with us nearly as long as has the formal insurance market, dating back at least to the 1575 establishment of the Office of Assurances in Great Britain to “coordinate and begin to control the writing of insurance” (Daykin & Cresswell, 2001). While regulatory efforts develop and change over time and across jurisdictions, regulation in the insurance sector generally falls into three categories: pricing, solvency, and market, the latter including product licensing and marketing, claims handling, market access,
and underwriting. As seems true for any regulated industry, debate over the appropriateness of governmental requirements is extensive and varied. Among economists, general agreement exists that the most socially beneficial industry regulations are those that assist in encouraging competitive markets. Such markets will not address issues associated with unequal wealth and income distribution or other societal concerns; yet the belief is that by encouraging competitive markets, private industry can perform its best for society. Other societal concerns can and should be addressed through non-private mechanisms, such as by NGOs and governmental programs, which are transparent and overt, limiting market distortions.

Within the insurance context, research suggests that the market demonstrates the key attributes of a competitive market, with many buyers and sellers, and reasonably open entry and exit; that is, concern over monopoly power is unwarranted. Joskow’s (1973) seminal work set the foundation for such consideration within the insurance markets, and generally has been supported over the years (see Klein, 2012 for a discussion). Within the academic literature on insurance regulation, most authors conclude that regulation is most appropriate when market failures exist, and these most often are found in situations involving asymmetric information (see Klein, 2012).

Market failures in insurance tend to arise due to greater levels of information and power held by insurance carriers relative to consumers. These situations are most common in the personal-insurance lines of business, which is where microinsurance is focused. Insurers in particular have greater levels of information and power regarding the riskiness of their portfolio, leading regulators to focus on solvency concerns. Other concerns arise out of the insurer’s control over contract wording and enforcement, which the consumer may not have the capability to understand or refute, directing attention to sales and claims adjusting practices.

Regulatory intervention is considered socially beneficial when the government holds superior capabilities to consumers in information acquisition and use. In the insurance sector,
these capabilities tend to exist when individual private monitoring is ineffective and/or excessively costly in comparison with the economies of scale and enforcement powers held by regulators (see Cummins, 1988). Under such conditions, government intervention can enhance market competition and thereby increase social welfare (see Klein, 2012; Skipper & Klein, 2000).

Before continuing, it is important to differentiate between market conditions leading to actual market failure and conditions resulting in undesirable market outcomes. The former offer a rationale for government intervention; the latter do not. Lack of affordable insurance coverage due to high risk may be undesirable from a public policy perspective, but typically is not improved by governmental intervention.³ Other efforts to mitigate risks and/or enhance individual resources are expected to be more effective in addressing these sorts of undesirable market conditions than would insurance regulatory interventions.

In an effort to define effective schemes, Skipper and Klein (2000) provide four criteria that should be met by insurance regulation if it is to “promote the twin goals of having a competitive and solvent insurance market.” These criteria, and sub-parts for each, are shown in Table 2.

We read these criteria as focusing on a few key goals: (1) encouraging market competition because the consumer is best served by competition rather than by regulation; (2) regulating only where market failures exist, which usually occur in respect to solvency; (3) applying regulations equitably to all insurers (specifically to locally and foreign domiciled insurers in like manner); and (4) assuring that regulatory rules and purposes are communicated in a way that is transparent and understood. These goals are consistent with the literature.

<tr>
<th>Criteria Sub-criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Regulation should be adequate</td>
</tr>
<tr>
<td>• Governments should enact and enforce laws that provide an effective framework for competitive insurance markets</td>
</tr>
<tr>
<td>• Governments should enact and enforce laws that establish reasonable solvency standards and regulation as the primary means of protecting the public</td>
</tr>
<tr>
<td>• As part of reasonable solvency regulation, governments should establish, make public, and enforce appropriate and consistent rules and procedures for identifying and dealing with financially troubled insurers</td>
</tr>
<tr>
<td>• Governments should establish an insurance regulatory agency that operates in the national interest and has sufficient resources to efficiently, effectively, and impartially enforce the nation’s insurance laws and regulations</td>
</tr>
<tr>
<td>• Governments should develop and implement pro-competitive insurance regulation in a way and at a pace that ensures adequate protection of the public but that proceeds without undue delay and is subject to a reasonable implementation timetable</td>
</tr>
<tr>
<td>2. Regulation should be impartial</td>
</tr>
<tr>
<td>• Governments should ensure that regulation and enforcement are applied with consistency and impartiality between competitors, irrespective of the nationality</td>
</tr>
<tr>
<td>3. Regulation should be minimally intrusive</td>
</tr>
<tr>
<td>• Insurance regulation should be limited to that which is (1) justified as providing meaningful protection; and (2) minimally intrusive to accomplish its purpose</td>
</tr>
<tr>
<td>• Subject only to that regulatory oversight essential to protect the public, governments should allow the market to determine: (1) what financial services products should be developed and sold; (2) the methods by which they are to be sold; and (3) the prices at which they will be sold</td>
</tr>
<tr>
<td>• Governments should ensure that insurance customers have access to information sufficient to enable them to make informed, independent judgments as to (1) an insurer’s financial condition; and (2) the benefits and value of its products</td>
</tr>
<tr>
<td>4. The regulatory process should be transparent</td>
</tr>
<tr>
<td>• Governments should make existing insurance laws and regulations easily available to the public, including to consumers and businesses and to insurers and other financial services providers</td>
</tr>
<tr>
<td>• In crafting proposed insurance laws and regulations, governments should: (1) make such proposals easily available to the public, including to consumers and businesses and to insurers and other financial service providers; (2) invite comment on the proposals; (3) allow sufficient time for interested parties to provide comments; (4) provide justification for decisions to accept and reject comments; and (5) establish and communicate a fair process by which decisions considered arbitrary or unjust can be challenged</td>

(b) Microinsurance

Microinsurance can be defined as “a financial arrangement designed to protect low-income people against specific perils in exchange for regular premium payments proportionate to the likelihood and cost of risk involved” (Churchill, 2007). This definition should suffice for a discussion of general regulatory themes.

We begin by noting the limited amount of academic research focused on regulation as it applies to microinsurance markets. Yanli (2009) discusses, but does not evaluate, the regulation of agricultural insurance in China, where regulatory authorities take an active role in developing agricultural insurance schemes through assuring government support for
research, data, market access, and customer protection. Describing and evaluating the Philippines microinsurance environment from a social policy perspective, Llanto (2007) proposes the need for a regulatory system that assures protection for policyholders while supporting the development of microinsurance markets. He does not take an economic approach to his analysis, nor does he detail the specifics of such a regulatory approach. Rather, Llanto’s work seems to be a call for further research that will help yield answers and ultimately generate solutions for the expansion of security to people in low-income classes.

A few studies focused on other aspects of microinsurance offer some evidence of regulation-induced problems in the development of microinsurance markets. Tight regulatory schemes (see, e.g., Asfaw & Jütting, 2007) and regulation-induced transaction costs (see, e.g., Pauly et al., 2006) are some of the problems reported. An issue that seems prevalent in these markets is one of trust or, rather, distrust by the community, especially of governmental entities. When passing new regulations, therefore, assurance that those regulations will be enforced is critical in order to avoid reinforcing the population’s perception of the government as untrustworthy (see Dlugolecki, 2008).

In addition to the academic literature, several NGOs and other supporting organizations (e.g., Microinsurance Network and Access to Insurance Initiative) have published detailed descriptions of the microinsurance regulatory environment in various countries, as well as suggested frameworks for sound microinsurance regulation (see, e.g., Chatterjee, 2012; Lester & McKee, 2012). Importantly, the international body of insurance regulators, the International Association of Insurance Supervisors (IAIS), also issued guidelines, which we specifically discuss below.
(c) Microfinance

Another set of literature helpful in evaluating microinsurance regulation is found in the microfinance field. Many microinsurance programs are connected to or derived from microfinance institutions (MFIs); therefore, we may well be able to gain insights from considering knowledge gleaned in MFI regulations. Existing work on regulation in microfinance emphasizes the need for:

- an industry-specific approach to MFI governance (see Mersland & Strøm, 2009),
- incorporation of country specificities in regulation to encapsulate the specificities of the macroeconomic environment and different stages of development (see Arun, 2005),
- sufficient regulatory capacity and quality (see Jalilian, Kirkpatrick, & Parker, 2007),
- recognition of the limitations of corporate self-controls in yielding desired outcomes when strong systems of transparency, monitoring and enforcement are lacking, a common condition in developing economies (see Graham & Woods, 2006).

3 CHALLENGES IN MICROINSURANCE REGULATION

As noted above, academic researchers argue that insurance regulation is socially beneficial in the presence of market failures associated with principal-agent conflicts and/or informational asymmetries. Within the microinsurance markets specifically, significant market failures have been identified (for a review, see Biener & Eling, 2012). These market failures stem in large part from uniqueness of the product and market, suggesting that microinsurance may be a setting that particularly justifies governmental intervention. In Table 3, we list issues somewhat peculiar to microinsurance as well as regulatory responses often suggested to address them. The following subsections discuss the appropriateness of such responses.
Table 3. Central Challenges in Microinsurance Regulation

<table>
<thead>
<tr>
<th>Issue</th>
<th>Possible Regulatory Response</th>
</tr>
</thead>
</table>
| 1. An effective definition of microinsurance should avoid encroaching on or distorting other insurance markets | ▪ Define boundaries to fit specific situations where market failures exist
▪ Avoid opportunities for market arbitrage |
| 2. Encourage innovations to reduce the influence of adverse selection and moral hazard that generate from relatively high administrative costs due to low coverage and low premium levels | ▪ Encourage low-cost distribution channels and innovative partnerships
▪ Facilitate licensing procedures that account for the lower product complexity and the preference for intermediaries familiar to the consumer
▪ Provide certainty of allowable returns, given the need for higher returns on smaller premiums for a market to develop |
| 3. Enhance product quality and consumer knowledge to address high levels of skepticism (lack of trust) | ▪ Identify and offer programs to enhance financial literacy, including understanding how the community benefits from some (but not all) members receiving compensation for losses
▪ Assure availability of underlying benefits, such as healthcare, covered by any available policies
▪ Assure high-quality claims payment and claims payment processes, including a defined complaint mechanism |
| 4. Facilitate the transition of small, informal microinsurance schemes to regulated entities | ▪ Consider capital requirements that are different from those of traditional markets
▪ Support access to reinsurance and other risk transfer solutions
▪ Provide training to assure a knowledgeable and capable workforce
▪ Enforce laws against corruption to build up trust |

(a) Define microinsurance to limit arbitrage and enhance market development

Any specific microinsurance regulation requires a definition of the product, market and/or institution in order to distinguish it from other insurance products, markets and/or institutions that are subject to a different set of regulation. To be effective, the definition ought to account for the characteristics of the product and industry that suggest separate regulation in the first place. An appropriate definition also will avoid encroaching on and/or distorting other insurance markets. That is, the definition and resulting regulations need to be written in a manner that limits incentives for regulatory arbitrage. To date, only six countries (Brazil, India, Mexico, Peru, the Philippines, and Taiwan) have specific microinsurance regulation. In these jurisdictions, three methods of categorizing microinsurance and microinsurers are employed. One is based on product coverage, such as the limit of insurance and/or premium falling below some designated level. A second is based on the market served, such as policyholders with incomes below a given threshold. The third is based on
characteristics of the entity taking on the risk (such as asset size) or, sometimes, the type of distribution channel (see IAIS, 2007; Churchill & McCord, 2012).

While a clear definition is important for deciding which contracts and activities are subject to the regulation, regulators also face the challenge that the definition be appropriately written so that actual market failures are the focus of the regulation. The concern is that an inappropriate definition may prevent some participants from entering the market, which could restrict product innovation and, ultimately, the goal of improved competition. Furthermore, variations in regulation across different market segments need to be designed to limit unwanted market distortions that generate from regulatory arbitrage. For instance, if lower capital requirements are implemented for products of a particular size, will insurers then seek means to sell more of those products than the market would support otherwise, by for example, selling two or three policies to the same individual, rather than one policy of the size desired by the consumer?

The question arises, then, as to whether these definitions address issues of market failure. In microinsurance we observe multiple areas of potential market failures associated with asymmetric information. We observe the standard issues of solvency, where the regulator is in a better position than the individual policyholder to implement successful monitoring of financial strength. Beyond this traditional area, we also observe significant asymmetric information in the form of adverse selection and moral hazard, far beyond what is encountered in the conventional insurance market. In the conventional market, insurers have access to various devices such as effective underwriting, pricing, and use of deductibles and exclusions to maintain acceptable levels of adverse selection and moral hazard. In the developing markets, however, data to estimate losses are less easily available, and perhaps more importantly, the consuming population is unfamiliar with underlying concepts of insurance. This lack of insurance knowledge often leads to distrust and discouragement when
losses are not covered for reasons that tend to be understood in the conventional insurance markets, such as for example, for pre-existing conditions.

These particular characteristics of microinsurance tend to mimic variations in existing product lines. For instance, we differentiate regulations across personal and commercial insurance, in part because of the perceived differences in consumer insurance expertise. Microinsurance demonstrates similar needs with an even more extreme lack of financial literacy. We take the position, therefore, that the definition of microinsurance ought to be one that distinguishes it as a unique product line. Some insurers will be specialized mono-line microinsurers. Others will be multi-line insurers with microinsurance as one line of coverage. We anticipate that the definition of microinsurance, therefore, will be a combination of target consumer (relatively low income) and policy form (generally low limits and simple coverage).

In making this recommendation, we also encourage regulators to recognize risk differences between the micro and conventional forms of coverage, differences that ought to affect capital requirements. Doing so will aid the development of mono-line microinsurers that otherwise are not able to meet the standard insurance capital standards, a topic we discuss further in the following pages. We also recommend that regulators be active participants in enhancing financial literacy, particularly among the low-income population.

(b) Encourage innovations that minimize administrative costs

A major problem on the supply side of microinsurance is that policy administration involves substantial fixed and variable costs; hence, as coverage amounts decline, administrative costs become a larger portion of the premium and, by extension, the portion of the premium devoted to pay claims declines. These are conditions under which adverse selection becomes more likely. Furthermore, efforts to reduce administrative costs, such as minimal underwriting and claims adjusting procedures, are also associated with increased adverse selection as well as moral hazard. In other settings, insurers have dealt with these
informational issues through underwriting and product mechanisms and the concern is that regulatory interference may harm the market rather than benefit it (see Herring & Pauly, 2001). Regulatory limitations on permissible underwriting criteria, while intended to expand coverage to a greater array of policyholders, can actually shrink product availability (see Browne & Frees, 2004).

A number of creative microinsurance innovations demonstrate that technology may be a key mechanism through which administrative costs can be reduced. Cell phones, for instance, have been used to issue policies, pay premiums, maintain health status information, and, ultimately, make claim reimbursements. Innovative distribution channels have been key to successful expansion of the microinsurance market (i.e., reaching a larger percentage of the target population; see Lloyd’s & Microinsurance Centre, 2009). Interestingly, some of these techniques are now being used in the developed market as well (see Burris, 2012). Such reverse innovations provide one rationale for extending regulations across the entire market rather than solely to the microinsurance market.

Similarly, organizations are entering into creative partnerships for purposes of expanding microinsurance availability. An example is Kilimo Salama’s partnerships across insurers, seed distributors, communication and weather satellite organizations, the government, and NGOs in Kenya. Each member of this partnership has a vested interest in market expansion and each contributes specific expertise to the success of the whole.

Sometimes these innovative mechanisms and partnerships, however, are not permitted by the regulator. Licensing requirements are intended to protect policyholders from insufficiently informed and potentially unethical agents and insurers. Yet Wiedmaier-Pfister (2004) argues that requirements for distribution channels often are either too high, thereby decreasing market resources, or not sufficiently restrictive, consequently neglecting customer protection. Achieving a balance between customer protection on the one hand and innovation
and market efficiency on the other is an important task for regulatory authorities generally, not just in this setting.

Cost-efficient techniques are particularly important in microinsurance because of the low premium value per policy. These techniques reduce adverse selection by yielding a larger portion of each premium unit to pay for losses. Similarly, the low premium value leads insurers to seek a higher rate of return on microinsurance than from other coverages. Incentives to enter the market are reduced when regulators forbid higher returns and/or fail to offer some sense of certainty about what is an acceptable return. This outcome is similar to the need in the microfinance area for higher interest rates on microloans than on conventional loans. Importantly, even those higher rates are still far lower than what individuals can obtain through informal means (see Aiyar, 2010). A definition of an “acceptable return” in microinsurance is thus needed.  

(c) Enhance financial literacy and availability of services

Another distinctive feature of microinsurance markets is the target population’s lack of experience with financial services in general and with insurance specifically. This situation often leads to a high rate of moral hazard and adverse selection. In a review of the literature on microinsurance, Biener and Eling (2012) find that asymmetric information appears to be especially problematic for microinsurance markets, which experience high rates of fraud, anti-selection, and moral hazard. There are a variety of reasons for this situation, including general distrust of governments and large organizations in many of the regions where microinsurance is most needed, as well as a lack of understanding of insurance by the target population. Even among people who have been exposed to insurance throughout their adult lives, the idea that one should receive something tangible in return for a premium is prevalent.  A recent interesting twist on moral hazard in insurance markets comes from the behavioral economics field where researchers have identified ethical “blind spots”; these occur, for example, when
we tell ourselves that adding the costs of car repairs that had nothing to do with the covered accident is legitimate because we have paid premiums for years without making a claim (see Bazerman & Tenbrunsel, 2011). Among a population new to the concept of insurance, ethical blind spots may be even more prevalent.

Below we discuss the important role played in the microinsurance market by small, informal insurers. Their importance generates from a variety of conditions, including an ability to address moral hazard and adverse selection. Another successful method in reducing moral hazard and adverse selection is implementation of programs that improve financial literacy. This is well illustrated by an experiment conducted by Karlan et al. (2011). They conducted a randomized field experiment in rural Ghana in which they offered two types of loans: crop price indemnified loans and loans without the indemnification (insurance) component. The indemnity component forgives 50% of the loan if crop prices drop below a threshold price. Both products were offered at the same interest rate. Loan uptake was high among all farmers, but both products were equally popular. Furthermore, households that demonstrated greater risk aversion were less likely to purchase the product with insurance, suggesting a lack of product understanding. This sort of evidence has led regulators and others, such as in Ghana, Brazil, and India, to initiate literacy campaigns.10

Encouragement of group insurance schemes also yields positive results in reducing moral hazard and adverse selection (see Biener & Eling, 2012). As observed in conventional markets, group insurance, where all group members are provided similar insurance coverage without individual underwriting, can be effective in maintaining low administrative costs. When those groups exist because of reasons other than the availability of insurance, they also can address issues of adverse selection directly (that is, members are not “selecting” membership because of the insurance). Some microinsurance mechanisms further structure coverage in a manner that encourages members to behave in a way supportive of the group rather than solely on their own behalf. Doing so will reduce moral hazard.
A key factor toward incentivizing insureds to be open, honest, and trustworthy, is for the insurance marketplace to deserve this type of trust. Underlying benefits must be made available before the insurance makes sense, while the claims adjusting process needs to be fair and honest, and not too restrictive. Especially among a population unfamiliar with insurance, a method to file complaints and be offered thorough and thoughtful responses to their concerns regarding claim denial is necessary for the community to support an insurance initiative. Without such an approach, the community quickly will become disillusioned and unwilling to participate in the market.

(d) Facilitate the transition of informal to regulated entities

Quite a bit of successful microinsurance is offered through small, local, somewhat informal providers and distributors. These could include, for example, a local religious entity or a community organization. The local and informal nature of the coverage tends to address consumers’ general lack of trust of outsiders and especially large bureaucracies because the salesperson and policyholder are likely to know one another or at least know of one another. Their close association with the community also can address concerns about adverse selection and moral hazard through agent knowledge of the community, lower monitoring costs, and ability to educate community members about insurance concepts (see, e.g., Dercon et al., 2006).

Less formal processes, however, are vulnerable to problems of their own, including the law of small numbers, possibly ill-informed providers of coverage, and even the potential to take advantage of the participating members through misplaced trust. This is an area in which regulation can assist by assuring appropriate product design and delivery mechanisms (see Wiedmaier-Pfister & Chatterjee, 2006) or by mandating appropriate licensing procedures. For example, in a pilot program in Brazil, researchers found that a local agent, well known to the community, was far more successful in generating trust in the insurance mechanism than were
the other agents. The study sponsors suggested that agent licensing might focus on moral character and reputation more than on technical skills, with those technical skills being taught as needed over time (see CNseg, 2011).

Various regulations, especially licensing and capital requirements as they are currently implemented, may constitute significant barriers for the smaller microinsurers and their intermediaries. Successful regulation will find the proper balance between those requirements necessary to protect consumers and those which may not be appropriate for specific microinsurance characteristics. Beyond the requirements itself, it is especially relevant for regulatory authorities to facilitate the transition process of informal schemes to regulated entities. Cull and Demirgüç-Kunt (2011) show negative effects of regulatory compliance in the microfinance domain. Specifically, they observe that for-profit MFIs reduce their outreach activities to women and in areas costly to reach (such as rural areas) in response to solvency regulations. Less profit-oriented institutions, such as NGOs, respond to solvency regulation by maintaining their outreach efforts at the expense of higher returns. Cull and Demirgüç-Kunt (2011) focus especially on the size differentials between MFIs and more conventional institutions in explaining their results. If these conditions extend to the insurance market, we would imagine that capital requirements and limited access to reinsurers will pose major barriers to small microinsurers, and may impede competitive markets, especially if not based on organizational risk.

We therefore recommend consideration of capital and reinsurance requirements that encourage overall risk management and diversification, providing a broader set of options to all insurers, including microinsurers, than may currently exist. Small microinsurers with limited product diversification may not require the same level of overall capital as would the insurers selling more complex and varied products (products with higher limits of coverage and a broader list of covered perils). A risk-based capital approach may be useful in this setting (see also IAIS, 2007).11
The potential systemic risk of small, focused microinsurers, however, may call for diversification across international boundaries through reinsurance or other alternative risk transfer mechanisms. For reinsurers, too, the opportunity to diversify across microinsurers functioning in numerous geographies could make their portfolios more efficient and effective. It is not uncommon in emerging insurance markets for regulators to require reinsurance from domestic carriers with the intent of supporting the local economy; yet, doing so can have a perverse effect of making the insurance market more expensive and too concentrated for the underlying risks. The result is a more lackluster market rather than one that is expanding.

We focus on support of local microinsurers and their agents in part because of the trust they engender. Lack of trust has been identified as a major barrier to successful development of microinsurance markets (see, e.g., Banerjee & Duflo, 2011). Therefore, in addition to support of the local microinsurers and their agents, governments should include elements of “fit and proper” licensing requirements that work towards assuring trustworthiness. The agents and insurer management must meet various requirements of honesty and fair dealing to be “fit and proper” members of the insurance community. Furthermore, requirements need to assure sufficient knowledge by those distributing coverage. Management education conducted by the regulator could be offered free of charge and on a voluntary basis to trusted members of the community to serve as local agents. In addition to the fit and proper requirements, the enforcement of laws against corruption, such as when an agent accepts premiums that are put into his or her own pocket rather than towards the issuance of insurance coverage, is an important element to build up trust.
4 REVIEW OF CURRENT REGULATORY SCHEMES

Insurance regulation varies substantially across jurisdictions and is often bewilderingly complex even within a single jurisdiction. Our discussion of general regulatory characteristics is therefore conducted at a basic level and only for purpose of comparing them with specific microinsurance regulatory systems. Microinsurance regulations are covered in more detail.12

(a) General global regulatory schemes

The IAIS has developed a set of “preconditions for successful insurance regulation.” These are broad underlying market and economic conditions that are necessary for an insurance market to flourish. They are not conditions within the purview of insurance regulators, yet the regulators have stated that these conditions are critical to their own success in developing a viable insurance market. The preconditions are listed in Table 4.

Table 4. IAIS General Preconditions for Effective Insurance Regulation

| 1. Sound macroeconomic and financial sector policies |
| 2. Well-developed public infrastructure |
| 3. Effective market discipline in financial markets |
| 4. Appropriate public safety nets |
| 5. Efficient financial markets |

The IAIS also has developed a set of “Insurance Core Principles (ICP),” which are intended to define a globally accepted framework for supervision within the insurance sector. The ICPs are envisioned as representing the highest level in the hierarchy of supervision, prescribing essential elements of a supervisory regime that promotes a financially sound insurance sector while providing an adequate level of policyholder protection (see IAIS, 2011). National regulatory standards are the next level in the hierarchy and can be linked to specific ICP statements, which can be related to the main areas of insurance regulation as defined by Skipper and Kwon (2007). The ICPs also clearly define the role and scope of the insurance supervisory authority.

Just recently the IAIS moved one step closer to providing microinsurance regulation by issuing an application paper on the “regulation and supervision of inclusive insurance
markets,” consistent with the G20 support of the Principles of Innovative Financial Inclusion. These efforts are viewed as being focused on microinsurance markets. Comments have been received on the application paper, and a working group of representatives from the IAIS and the Microinsurance Network has been formed (see IAIS, 2012).

(b) **Existing microinsurance regulatory schemes – generally**

As mentioned previously, six countries provide insurance regulation focused solely on microinsurance (Brazil, India, Mexico, Peru, the Philippines, and Taiwan). Moreover, a number of other countries are developing or implementing microinsurance regulation at the moment (Pakistan, South Africa, CIMA countries). We present an overview of the regulatory environment in these two sets of countries (those that have implemented, and those considering implementing, specific microinsurance regulations). Our intention is to evaluate the extent to which the existing mechanisms address issues of market failure and therefore qualify as socially beneficial regulatory systems.

We begin with consideration of the extent to which the IAIS preconditions for effective insurance regulation exist. While these preconditions are outside the sphere of influence of insurance regulatory authorities, they are critical to market success.

There are many possible proxies for measuring the general environment of insurance markets; we use indicators from the World Bank (2011) and the Heritage Foundation (2012). In Table 5 we present measures for each precondition for each country/region in which specific microinsurance regulation either exists or is under serious consideration.\(^\text{13}\) We also provide comparison data for the highly developed markets of the United States, the United Kingdom, and Germany.

Judging from the proxies for regulatory environment, the nations in which specific microinsurance regulation exists, and especially where such regulations are being considered, have quite some distance to travel before reaching the same level as the three highly developed insurance markets. In some instances, it could be more important to focus on achieving basic government, health, and welfare conditions than to expend energy improving insurance regulation. However, one purpose of expanding microinsurance markets is precisely to foster economic development. As Outreville (2012) notes in his recent survey of the literature, researchers find significant evidence linking a growing insurance market to a growing economy. The causal direction, however, is not clear and may be mutually reinforcing.

We are intrigued by variations across these countries and regions. Africa has seen significant growth of the microinsurance market (see Churchill & McCord, 2012), and yet it lags far behind in basic economic conditions. South Africa is the exception in these data and, not surprisingly, because it’s insurance market has been active for a longer period and is more advanced. In contrast with most African nations, Taiwan demonstrates a relatively strong...
and developed government and economy. Specific regulations for microinsurance products, therefore, may be appropriate more widely than just in emerging economies, given Taiwan’s introduction of such rules. Perhaps lessons learned from microinsurance markets in emerging economies offer opportunities for “reverse innovations” that can assist in extending economic advantages to low-income populations in more advanced economies.

(c) Existing microinsurance regulatory schemes – specifically

(i) Defining the product and the market

If specific rules are to be applied to microinsurance products and markets, those products and markets need to be defined. As noted above, three approaches to this issue have been employed to date: define the product, define the target population, or define the risk-taking entity. Brazil, India, Mexico, and Peru all define microinsurance in terms of product characteristics, while Taiwan defines microinsurance in terms of the “economically disadvantaged” target population to be served, that is, income levels of the target population. The Philippines uses both a product definition and an institutional definition through what are referred to as Mutual Benefit Associations (MBA), entities that are non-profits designed primarily to offer life, medical, and unemployment benefit coverage to association members. Not all microinsurers must be MBAs; rather, MBAs are given special recognition as microinsurers.

Relevant product characteristics typically incorporate lower and upper limits for coverage and upper limits for premiums. In India, explicit boundaries are set for coverage levels, contract terms, and insured age. The new microinsurance regulation in Brazil clearly sets maximum levels of microinsurance coverage besides also defining the general classes of insurance products, terms of coverage, exclusions, means of premium payment and other characteristics in different lines relatively precisely. In 2009, Peru significantly revised its microinsurance regulation by moving from a quantitative definition of microinsurance to a
qualitative definition referring to the provision of protection for low-income populations without setting limits on either coverage or premiums (see Ingram & McCord, 2011). The regulatory authorities explicitly address the problem created by defining microinsurance on a quantitative basis by arguing that limits on prices and benefits are potential impediments for the development of innovative microinsurance products (see SBS, 2010). We believe that the key issue in selecting among these (and possibly other) alternatives is to consider where information asymmetries will be greatest, and define the product and market to incorporate those situations.

(ii) Distribution

Regulators set relatively strict boundaries on microinsurance distribution, often narrowly defining the types of entities or individuals allowed to sell coverage. India’s rules contain four categories of distributors: brokers, agents, corporate agents, and specific microinsurance agents approved only for non-profit institutions. Microinsurance agents sell only microinsurance and are granted more favorable regulatory requirements (see IRDA, 2005). Brazil and the Philippines implemented a similar system for specific microinsurance agents and brokers but it is not restricted to non-profit organizations. These agents and brokers are not permitted to sell other products and are subject to less strict licensing requirements in return (see Philippine Insurance Commission, 2010). Taiwan authorizes the distribution of microinsurance through agents and brokers who are permitted to sell either conventional or microinsurance (see Taiwan Insurance Bureau, 2009).

(iii) Product design and pricing

In most countries where specific microinsurance regulation exists, specific regulations have been implemented regarding product design and pricing. Both India and the Philippines, for example, require that microinsurance policies be easily understood and bear a specific obligatory microinsurance logo. The Brazil regulations also require simple terminology that is
easily understood by the insured. Taiwan includes these same types of requirements and also limits the term of coverage to no longer than one year and no more than one peril covered per policy (see Taiwan Insurance Bureau, 2009). Restricting the number of perils covered under one policy makes sense when it comes to reducing product complexity to account for low levels of financial literacy of the target population. It also is appropriate when data availability is limited, restricting the ability to analyze underlying risks as well as dependency among risks (see, e.g., Biener, 2013). Single-peril policies, however, limit the opportunity to experience efficiencies of bundling together coverages for several causes of loss. Furthermore, the policyholder is not particularly concerned with the precise peril that causes loss, just that loss occurs. If the target population is likely to need and want coverage for more than a single peril, it may be wise to devise a method to permit these broader contracts.

Rate restrictions similarly have the potential to dampen market opportunities for the target population. While insurance premiums are subject to some form of regulatory intervention in most areas around the globe, such restrictions tend to yield undesired outcomes, even when done with the best of intentions. Research on the US market consistently finds perverse effects of pricing restrictions, such as the reduced coverage availability in the US auto market (see Weiss, Tennyson, & Regan, 2010; Harrington, 1990). Similarly, rate restrictions in voluntary private health insurance markets intended to increase access to health insurance for high-risk individuals (e.g., with chronic diseases) sometimes lead to the exclusion of those risks from health coverage due to the insurers’ anticipation of losses from coverages for high-risk types (see Van de Ven et al., 2000).17

The microinsurance market also has been subject to pricing restrictions and distortions, either through upper limits placed on premiums or through the use of direct premium subsidies. Premium subsidies may have positive short-term effects by increasing demand and reaching underserved populations; however, long-term incentives and willingness to pay might be detrimentally affected, leading to higher aggregated costs to
society as a whole. These market interventions often result in higher premiums as well. When governments and, by extension, their populations believe that access to a product or service ought to be increased, methods that increase resources rather than reduce prices tend to be most effective. Hudon and Traca (2011), for instance, identify improved efficiencies for MFIs that receive “smart subsidies,” which are those that are definitive, time-designated, and limited. Furthermore, the subsidies are most effective when they go to the lending institution rather than the consumer.

We recommend, therefore, that governments not subsidize insurance premiums directly. Rather, we recommend that efforts be made to expand insurance for underserved populations by: (1) working to improve earning opportunities for these underserved populations so that they can afford insurance; (2) educating the populace about risk and insurance to increased demand as well as lessen moral hazard; (3) providing mechanisms to improve insurer efficiency such as sharing data and expertise; and (4) working toward lowering the cost of and increasing access to needed services, such as healthcare.

In setting regulatory policy, true market failures as distinguished from undesirable market outcomes should be the focus. Once market failures are identified, government interventions that will address those failures most effectively should be considered. Specific areas where governments likely have some advantage include (1) educating, both the public and the insurers (e.g., salespeople, claims adjusters, underwriters, actuaries); (2) providing a platform to share data to deal with concerns of small numbers (e.g., loss, weather, health, or mortality data); and (3) lowering regulatory barriers, for the industry as a whole, perhaps, not just microinsurance.

(iv) Prudential (solvency)

Many researchers suggest that prudential regulation, that is, solvency, is the primary area where insurance regulation is obviously supported by an underlying economic rationale.
Insurers tend to have information regarding their risk-taking strategies that is superior to that known by policyholders (see Klein, 2012 for a discussion). This is precisely the sort of asymmetric information situation where regulators may be able to achieve a socially beneficial outcome through interference with the market.

For the past several decades, solvency regulation has been a major focus of regulatory bodies and academic researchers, with the resulting development of risk-based capital standards in the United States, Solvency II in the European Union, and initiatives in New Zealand, Switzerland, and elsewhere urging the greater use of modeling and principles-based approaches to solvency requirements. The developing world, however, still tends to rely on simple rules of minimum capital levels in absolute terms (i.e., without considering risk). Holzmüller (2009) and Cummins, Harrington, and Niehaus (1994) offer evidence of concerns with the rules-based approach as well as a set of criteria to evaluate the appropriateness of insurance solvency regulations. In the light of potential weak enforcement of regulation in microinsurance markets, it is, however, not clear whether principles-based approaches to solvency requirements will eventually result in the desired outcomes (see Di Lorenzo, 2012).

Capital requirements are a source of concern for many local microinsurers, a concern that is supported by studies showing that capital requirements often are too high for the small policies sold by locally organized microinsurers (see, e.g., Wiedmaier-Pfister, 2004). In India, for example, capital requirements for microinsurers are equal to those of conventional insurance companies (see Sinha & Sagar, 2009). High capital requirements can hinder the growth of the microinsurance industry by implicitly requiring more costly risk transfer solutions such as reinsurance from domestic reinsurers (rather than from the international market as a whole). Some support for this hypothesis is found by Berry-Stölzle, Hoyt, and Wende (2010), who observe that larger insurers in emerging markets, those that can more easily meet capital requirements stated as an absolute amount and who have greater access to alternative capital sources, have higher performance.
Initial capital requirements also hinder market entry. In India, for example, the initial capital requirements for registering a microinsurance business amount to INR 1 billion (US$ 18 million). Similarly, the Taiwan regulatory authority applies the same capital requirements to microinsurers as to conventional insurance companies, with the exception of group-insurance policies for which other, not explicitly specified, rules may apply (see Taiwan Insurance Bureau, 2009). The minimum initial capital requirement for a locally incorporated insurance company is NT$ 2 billion (US$ 67 million; see Wong, 2011).

The Philippines, in contrast, implemented a separate system for MBAs not able to meet the minimum capital requirements. These associations must register with the regulatory authorities and increase their capital over time. The initial capital requirement is PHP 5 million (US$ 120,000). This approach has proven successful in encouraging previously informal and unsupervised microinsurers to approach formalization under the regulatory framework (see Bester, Chamberlain, & Hougaard, 2008). After amending the microinsurance regulatory framework in 2010 (see Philippine Insurance Commission, 2010), the Philippine government increased capital requirements for all insurance companies while also introducing separate microinsurance capital regulations. Microinsurers, other than MBAs, are now required to hold PHP 500 million (US$ 12 million; see Philippine Department of Finance, 2012). This is a substantial sum, but lower than that required of other insurers, some of which are required to hold PHP 1 billion (US$ 24 million). MBAs continue to enjoy the lower requirements as noted above (see Philippine Insurance Commission, 2006). In addition to initial capital requirements, the Philippines adopted ongoing performance requirements for solvency, liquidity, and leverage (see Philippine Insurance Commission, 2011).

South Africa is in the process of implementing a new comprehensive regulatory framework for microinsurance that is expected to come into effect in 2013. Currently, microinsurers fall under the regulation for long- and short-term insurance, for which minimum capital requirements of ZAR 10 million (US$ 1.20 million) and ZAR 5 million
(US$ 0.60 million) are applicable, respectively (see Bester et al., 2009). Under the new microinsurance regulatory framework, ZAR 3 million (US$ 0.36 million) is envisioned as upfront capital (see South African National Treasury, 2011).

Other African countries, specifically the CIMA countries, are on a path to separate microinsurance regulations, having agreed in 2012 to implement new microinsurance regulations (see Microfact, 2012). Pakistan also is on track to develop microinsurance regulatory rules and is in the process of drafting rules in consultation with stakeholders (see Abores, 2011).

Capital requirements in developed insurance markets such as EU countries and the United States include both a floor or minimum requirement and a risk-adjusted level above that floor based on the insurer’s own characteristics. Somewhat surprisingly, the minimum requirements in some of the micro markets are relatively high even when compared with the EU, where insurers are required to hold a minimum of US$ 2.7 million (non-life) and US$ 3.9 million (life) of capital (see European Parliament & Council, 2009), and the United States, where minimum capital requirements vary by state, but are in the range of single-digit million US$ amounts (see NAIC, 2012). These figures make the microinsurance capital requirements seem somewhat inappropriate. We encourage regulators and governments to consider lower requirements as well as, and perhaps more importantly, risk-based requirements. The IAIS recommends consideration of “proportionality,” which would adjust requirements based on an insurer’s size and risk status. We further suggest that policymakers work to make rules consistent across all jurisdictions to limit regulatory arbitrage.

5 CONCLUSIONS

Private market mechanisms intended to address various social issues often referred to as “social entrepreneurship” or “social innovation,” have expanded significantly in the past 20 years. Perhaps Muhammad Yunus’s Grameen Bank, for which he received the Nobel Peace
Prize, is the best known of these. Social, cultural, and economic conditions all have played a role in the decreasing involvement of governments and the increasing use of private markets in addressing social issues. Microinsurance fits well within this framework.

Swiss Re (2010) estimates a potential of US$ 33 billion in premiums from a robust worldwide microinsurance industry market to low-income, but not destitute individuals, only a small fraction of which has been tapped to date. An enormous potential exists not only for insurer revenues but also for improving the lives of many. To make this a reality, we need to understand why it is not in place already. A number of authors highlight problems in the microinsurance market, including financial literacy (or lack thereof), trust in governments and outside organizations (or lack thereof), administrative costs of product sale and delivery, and the basic availability of underlying services (e.g., healthcare). In this paper, we evaluate the regulation of microinsurance with the aim of identifying those areas where regulators can assist (and those where they can hamper) the development of microinsurance markets.

We make the following conclusions and recommendations. First, we encourage regulators to avoid developing regulatory arbitrage between conventional and microinsurance markets. Specifically, we encourage clear boundaries between the two business forms so as to limit undesired market distortions.

Second, we encourage regulators to appreciate the differences between microinsurance and conventional insurance markets, developing programs that address the uniqueness of each. Early efforts in developing microinsurance products as well as regulation tended to treat the fields the same, just smaller policies in the microinsurance domain. As more nuanced approaches to the microinsurance market have emerged, greater successes have been experienced as well (see Churchill, Dala, & Ling, 2012).

Broadened distribution channels, not just for microinsurers, but across the spectrum of insurers, may be appropriate as technology evolves. Similarly, risk-based capital and reinsurance requirements will improve all underlying insurance mechanisms.
We also encourage regulators to consider financial literacy initiatives. There is good reason to believe that such initiatives can significantly improve the lives of many. This type of activity also meshes well with the governmental goal of providing security to the populace. Who better to undertake the role of enhancing financial literacy than one without a vested interest beyond true understanding?

Lastly, we encourage our academic colleagues to engage in research on this topic, and insurers and regulators to freely provide data for such research. Not only will the research aid in developing successful microinsurance markets, but it may well lead to successful innovation in the conventional markets.
REFERENCES

Taiwan Insurance Bureau. (2009). Directions for insurance companies to engage in microinsurance business. New Taipei City, Taiwan.

1 We believe that microinsurance is not likely appropriate for people at the very bottom of the pyramid; therefore, our estimates of the market may be more in the range of 1.5 to 2 billion individuals.

2 Being relatively new, microinsurance has not yet received extensive specific regulatory attention. Just six countries provide insurance regulation focused solely on microinsurance. India was the first in 2005, followed by the Philippines (2006), Peru (2007), Mexico (2008), Taiwan (2009), and Brazil (2012). Other countries, notably Pakistan, South Africa, and a coalition of other African countries, are either considering or in the process of implementing specific microinsurance regulation. The coalition of African countries is the Inter African Conference for the Insurance Market (CIMA). Member countries are Benin, Burkina Faso, Cameroon, the Central African Republic, Congo, Côte d’Ivoire, Gabon, Equatorial Guinea, Guinea-Bissau, Mali, Niger, Senegal, Chad, and Togo.

3 Programs designed to expand coverage, such as limitations on health insurance underwriting restrictions (see Browne & Frees, 2004; Hoffman & Browne, 2012) tend to have adverse effects of higher prices and in some instances lower supply. Similar effects have been documented in efforts to place caps on prices (Klein, 2012; Weiss, Tennyson, & Regan, 2010; Harrington, 1990, among others)

4 Regulatory arbitrage can occur when there are two or more sets of regulations applicable to a microinsurance product and/or insurer; e.g., when a product qualifies for both regular and microinsurance regulations. In such a situation, insurers will naturally classify their products such that costs (e.g., capital requirements) are minimized.

5 Pakistan, South Africa, and other African countries are considering specific regulation, and are likely to implement it soon.

6 For example, some countries define microinsurance with regard to products addressing a specific target population in a certain range of income. Setting such thresholds is challenging and likely excludes some of the potential target population.

7 It is likely that those insurers offering microinsurance only (i.e., mono-line microinsurer) are required to hold more equity capital as compared to insurers offering multiple lines including an equal line of microinsurance business (i.e., microinsurance as business line) because of lower diversification of risk. However, compared to approaches of simple minimum capital rules for all insurers presently applied (see Section 4(c)), significant reductions of capital requirements are to be expected for the microinsurance space if based on risk.
Around the globe, insurance prices are regulated in a variety of ways. Sometimes they are capped, sometimes the assumptions used to set them must be approved, sometimes they must follow principles of being “adequate,” “not excessive,” and “not unfairly discriminatory.” This latter set of statements is found in most US jurisdictions, with interpretation open to the regulator. Adequate typically is connected with solvency concerns, while “not excessive,” would connect with an acceptable return to insurers, after considering operating and loss costs. For low-premium products, a higher proportion is expected to go to the insurer simply to make the effort worthwhile. As a “return,” the payment can look large. For example, one that allows profits commensurate with the higher risk of microinsurance. Another question which has been studied in this context is the question of the optimal ownership form for providing microfinance. Most providers, both historically and today, are non-profit organizations or cooperatives, while policy papers advocate shareholders firms (see Mersland, 2009).

According to a study from GDV (2011), more than 20% of Germans consider insurance fraud to be a “trivial offence” which is committed by almost everyone at least once.

The Brazilian Insurance Confederation (CNSeg) has initiated an interesting program titled Estou Seguros and the Microinsurance Academy (MIA) in India has implemented a variety of creative programs; these are just two of many other examples.

One major issue with regard to the estimation of the microinsurer’s risk and the required capital is that small microinsurers may not have the resources needed to complete such analyses effectively. Here is an instance where the regulator could play an important role by undertaking much of the analysis, developing standard models as well as providing technical support.

Throughout the paper we do not discuss Sharia-conforming insurance products (Takaful) in detail although these also can be interpreted as a kind of regulation. We refer to El-Hawary, Grais, and Iqbalb (2007) and Pepinsky (2013) for more details about Sharia-conforming financial products.

In South Africa, draft microinsurance legislation is supposed to be submitted to parliament in early 2013 and implementation is expected toward the end of 2013/2014. The countries of CIMA signed an agreement to implement microinsurance regulations but we are unaware of definite implementation plans. Pakistan currently is in the first consultation phase of its proposed microinsurance regulatory framework, which is expected to conclude at the end of 2012.
South Africa has long supported the insurance industry, with the Insurance Institute of South Africa dating to 1898. The populace, therefore, has a stronger knowledge base and familiarity with the industry than in many other developing nations.

The International Monetary Fund (IMF) classifies Taiwan as an advanced economy (see IMF, 2012).

Microinsurance agents and brokers do not have to pass the regular licensing examination, but instead must participate in an approved training program and take a final examination (see Philippine Insurance Commission, 2010).

Insurance rate restrictions below what the market would yield always imply a cross-subsidization scheme between high-risk and low-risk types that will only be viable if the insurer has a sufficient share of low-risk types that compensate for the losses from high-risk types. Adverse selection effects may, however, easily put the viability of the scheme at risk (see Van de Ven et al., 2000).

Evidence for undesired market distortions from subsidies can be found for agricultural markets, flood insurance in the United States, and even some microinsurance markets. Subsidizing microinsurance may create incentives for risky behavior and permanently reduce willingness to pay (see Latortue, 2006). For example, in India, a subsidized insurance premium was provided for individuals below the poverty line. After two years, the subsidy was removed; less than 30% of the members wanted to renew their policies. If subsidies are granted to increase access of high-risk types, e.g., to health insurance, there is huge potential for adverse selection into the insurance pool because low-risk types will not be willing to pay substantially more for the coverage and will drop out of the pool, resulting in increasing average losses (see, e.g., Weiss, Tennyson, & Regan, 2010).
Exam 6 International Study Note – Solvency

Ralph Blanchard, FCAS

Abstract

The syllabus for Part 6-I includes papers from a variety of organizations produced over the relatively recent past. Despite our best efforts in searching for worthwhile material, some of those papers are dated in certain areas, contain information more focused towards life and annuity contracts rather than property/casualty contracts, or were not as clear as we would have liked. This study note attempts to fill those gaps in the other syllabus materials.

The study note is organized by Syllabus reading, including page numbers (when relevant) where a need to supplement, update or correct that material was identified.

1. OVERALL

The Broad definition of payments to policyholders
Several of the readings in the syllabus reference payments to policyholders. This should be interpreted broadly to include both payments to and on behalf of policyholders. For example, the claimants that might be paid under policies covering liability to third parties (such as mandated motor coverage in many countries) are not the policyholders themselves but people suing the policyholders.

Total Balance Sheet approach

This concept is alluded to by several of the readings, but not always fully defined. The basic concept is that the amount of assets needed to cover the risks of an insurer is a function of the risks on both sides of the balance sheet and how those assets and liabilities are measured. Under this concept the capital requirement cannot be viewed in isolation of the accounting. A change in the accounting system should result in a change to the required capital requirement. For example, if the only assets were cash (i.e., completely risk-free) and the only risk was misestimation of liabilities, if the solvency requirement was to cover the risk of liabilities reaching 100, then a liability
valuation of 70 under a conservative accounting system would require a capital requirement of 30. If those same liabilities were valued at 60 under a less conservative system, then the capital requirement would be 40. Under such an approach the degree of risk margin, for example, is not a solvency concern as long as the capital requirement reacts to that risk margin appropriately\(^1\).

As another example of the above concept, assume a balance sheet with risk in both assets and liabilities. If the assets were valued conservatively under a given accounting system, then the capital requirement would be lower than it would if the assets were valued aggressively. The former approach (conservative valuation of assets) might result in some cushion for risk on the asset side of the balance sheet, offsetting the need for the amount of capital to be reported. Aggressive valuation of assets would lead to a higher requirement for reported capital.

**Hedging**

Hedging of financial market risks is fairly common for certain types of life/annuity contracts but is much less used for P&C contracts. One reason for this is that the payout for most P&C contracts is not a function of interest rates or equity markets, so there is less need to hedge those types of risks.

2. **SPECIFIC READINGS**

**Reading: IAIS Core Curriculum 5 - Solvency - Principles and structures**

(We acknowledge that there are a number of typos in the early pages of this reading. Please excuse these – we do not believe they are material to the usefulness of the material.)

---

\(^1\) There may be other reasons to set a certain accounting approach to risk margins. Some accounting systems may desire to replicate the value a market would place on the liabilities if transferable, and market values generally reflect the risks of the items being transferred via risk margins. Some would want liability values to be set at a certain confidence level. Others might not want to include risk margins in liability valuations at all, due to estimation uncertainty, relying entirely on the capital requirement to cover the lack of margins.
On page 9 of this reading (Section 1.1.3) there is a discussion of various perspectives regarding solvency. The middle bullets of this list (Inforce, “Break-up or winding-up”) are generally focused on life/annuity products and/or may be focused on certain jurisdictions such that they are not totally relevant to many property/casualty (P&C) practitioners. Clarifying remarks for those bullets, as well as the “merger” bullet, are as follows:

- **Inforce** – This bullet point is discussing the solvency option of “runoff”, whereby an insurer stops writing new business as it runs off existing liabilities and obligations. While this may be limited to “in force” policies for a life insurance or annuity writer, the runoff obligations of a P&C insurer would include claim liabilities for in-force and expired policies. For certain products and jurisdictions, a majority of these runoff liabilities can come from expired policies. So, where this bullet point mentions “Inforce” please interpret that to mean “Runoff” including claim liabilities. As mentioned in the source material, such a runoff can be voluntary or can be a forced runoff at the direction of the supervisor.

- **Break-up or winding-up** – A major component of this bullet point, and how it differs from the previous “runoff” bullet point, is via the transfer of existing obligations to another insurer. The candidate should be aware that this is much more common for life/annuity products than for P&C products and may actually be prohibited in some jurisdictions absent policyholder consent. While existing obligations may not be subject to transfer, a supervisor may be able to salvage value from a P&C insurer windup by the sale of customer lists or renewal rights from the failed insurer, or potentially even some limited product lines, especially if the product line at issue has been profitable in the past.

- **Merger** – In some jurisdictions a supervisor may be able to force a merger of the failed insurer with a solvent insurer, but this is not always possible. The availability of this option is dependent on the local supervisor’s authority. Not all jurisdictions give the supervisor such authority.

Page 12 (section 1.4) includes a list of risks faced by an insurer. That list in the text is “underwriting, credit, market, operational, and liquidity risk”. The reader should be aware that underwriting risk here is meant to include both that related to premiums and that related to reserves. Premium risk includes the risks of mispricing (i.e., setting prices that do not reflect the expected costs), mis-underwriting (not selecting the types of risks anticipated in the pricing), and event risk (e.g., unusually bad whether under the policy period for property coverage). Event risk is higher when the exposures are
concentrated in one particular area (such as one flood plain, one industry facing higher levels of lawsuits, etc.). Reserving risk is the risk that actual losses will be different from the reserve estimates. Reserving risk typically (but not always) remains until claims are closed and future claim reports (on prior events) are highly unlikely.

With regard to liquidity risk, much of the current thinking in the context of solvency regulation is that liquidity risk is not addressed via a capital requirement, but via more prudent management of potential cash sources versus cash demands. In other words, it is largely avoidable or subject to substantial mitigation via the investment strategy of an insurer.

Liquidity risk can be extremely high for a bank, and can also be material for a life insurer, but generally is much smaller for P&C insurers. The reason for this difference is the lack of a financial call feature on most P&C liabilities. Rather than being instantly callable on demand (as in a bank’s checking account deposits), P&C claim liabilities are only paid after a covered event, and then only after an adjustment, negotiation, and settlement process. Ways of addressing liquidity risk are currently being investigated by the IAIS (as of early 2021).

“Matching” relative to P&C liabilities

Page 16 of the source material lists “Matching of assets and liabilities” as one of the essential elements of a solvency regime. The candidate should be aware that this is not exactly the case for most P&C products but was probably written with life/annuity products in mind. For many (most?) life insurance and annuity products the cash flows are highly predictable relative\(^2\) to P&C products, and in some cases such products have financial call provisions\(^3\) or interest rate sensitivities. As a result, matching of asset flows closely to life/annuity liability flows can be very achievable and may be absolutely necessary for solvency purposes. But the cash flows for many P&C products are uncertain both as to amount and timing.

It is generally possible to match asset flows to expected P&C liability flows, but actual liability flows are almost certain to be different from those expectations, in some cases materially so. As those expected flows are subject to re-

\(^2\) Both life insurance and annuity products have contractually defined (stated) payouts that require no negotiations. The payouts are also based on the subject individuals death or survival, with mortality trends generally very stable over time – at least from the perspective of P&C claim trends.

\(^3\) A financial call option in the insurance context allows the policyholder/claimant to demand immediate cash payment on the policy. In the context of life/annuity policies this relates to surrender provisions.
Solvency

estimation every reporting period (at a minimum due to actual to expected payout differences during the period), any attempt to match asset flows to those new expectations would require rebalancing the asset portfolio every reporting period, which can result in material transaction costs every reporting period. There also needs to be consideration of what happens when the liability flows.

for a period are much greater than expectations. A strict “matching” approach could require untimely liquidation of assets. Therefore, the focus for P&C companies are typically on asset/liability management, not asset/liability matching. For example, the asset portfolio may be managed such that the duration of such assets does not differ materially from the duration of the expected liability flows, as well as maintaining sufficient liquidity such that aberrations in cash flow demands from period to period do not require untimely asset sales. In short – asset/liability management is the approach taken by most P&C companies and not asset/liability matching.

There is a related issue in certain other readings in the syllabus (e.g., paragraph 6.103 of A Global Framework for Solvency Assessment) regarding “replicating portfolios”. Replicating portfolios are portfolios of assets that mirror the reaction of the liabilities to certain stresses, such as an interest rate increase. Such portfolios are generally not relevant to P&C liabilities, where the principal risks are non-financial market risks such as weather, accidents, and court decisions. Instead, it is more common to hear mention of “reference portfolios” regarding P&C asset/liability management. Reference portfolios are asset portfolios with the same expected cash flows as the liabilities, but whose change in value due to an event does not necessarily mirror the change in liability value due to that event.

Solvency assessment vis-à-vis balance sheet

Section 2.2 (page 17) states that “Solvency is fundamentally an assessment of an insurer’s current and, perhaps, prospective, balance sheet”. For P&C insurers this is a little misleading in that many of the risks (such as weather for property insurers) arise from the income statement results and may never show up on the balance sheet other than reduced levels of assets or equity after the event. This is alluded to later in the first paragraph of this section in the discussion of “many exposures … do not show up on the balance sheet”.

Catastrophe risk

That same section mentions catastrophe risks as a source of solvency concern. The candidate should be aware that this is increasingly being addressed using catastrophe models (for both internal risk management and statutory minimum capital requirements). Third-party vendors are already well-established for the hazards of...
Exam 6 International Study Note – Solvency
earthquake and tropical storms (hurricanes, cyclones, typhoons). Models have also been created for other hazards such as floods, terrorism, and hail.
The purpose of this study note is to educate actuaries on certain basic reinsurance accounting topics that may be omitted in other syllabus readings. Specifically, this study note provides examples of how ceded reinsurance impacts an insurer’s financial statements and key financial metrics.

**Ceded Reinsurance Impact on Financial Statements**

The book “Reinsurance Principles and Practices” by Connor Harrison lists the following six principal functions of reinsurance.

1. Increase large line capacity
2. Provide catastrophe protection
3. Stabilize loss experience
4. Provide surplus relief
5. Facilitate withdrawal from a market segment
6. Provide underwriting guidance

This paper will give an example of each of these types of reinsurance, and examine the impact to the ceding company on the following:

- Surplus
- Loss reserves
- Unearned Premiums
- Leverage ratios
- Income statement

The financial statements shown in the examples follow the SAP convention of offsetting ceded liabilities against gross liabilities.

1. **Increase large line capacity**

This example deals with the situation where a company is only willing to expose itself to a certain amount of loss per policy, but portions of its potential market demand greater coverage.

**Beginning Assumptions (the “Without” column):**

- XYZ insurance company writes homeowners insurance. It is unable or unwilling to write policies for homes with insured values over $500,000 without a suitable reinsurance program.
- XYZ writes $1 million of annual premium for this market, in a steady state with a level premium volume. The loss ratio is 75%. The only expense is commissions, which equal 20% of premium.
- Loss reserves = $750,000 and surplus = $1.5 million. Since XYZ is in a steady state, reserves and surplus are constant throughout the year.
- XYZ holds cash equal to 10% of gross loss reserves, agent balances equal to 10% of premium, and the remainder of its assets in bonds. The bonds and cash earn investment income at a rate of 5%.
- There are no income taxes.

**Altered Assumptions (the “With” column):**

- XYZ buys a “surplus share” pro rata reinsurance treaty that cedes premiums and losses for higher valued homes, with the ceding percentage for each policy equal to the excess of the home value over $500,000 divided by the total home value. (For example, for a home worth $625,000, the ceded percentage would be 125/625, or 20%.)
- This is the only reinsurance purchased by XYZ.
- The altered assumptions again reflect level premium volume and a steady state, in which XYZ has been writing identical business over a period of years.
• With access to the higher-value market, XYZ writes 40% more business and achieves $1.4 million in gross written premium. However under the treaties it cedes $300,000 of premium.
• The loss ratio remains 75% on both net and ceded business. However reserves increase relative to loss, because claims on more expensive properties take longer to develop.
• The expense ratio remains 20% of net written premium. The reinsurer pays a ceding commission to compensate for commissions on ceded business, so there is no net additional commission on ceded premium.
• Agent balances remain equal to 10% of premium, of which a portion, equal to the percent of premium ceded, is due to the reinsurer.
• We arbitrarily assume only a small increase in surplus, matching the increase in current year income.

Analysis of impact (from Exhibit 1)

- Surplus – We assumed no impact on surplus other than earnings on additional business opportunities. In reality, given the additional premium and reserves and reinsurance collectability risk, the ceding company may desire (or be forced to) hold more surplus to support these greater risks. Alternatively, it could decide to reduce volume to retain the same level of surplus relative to risk.
- Loss reserves – Both gross and net loss reserves increase, partly due to increased premium volume and partly due to the nature of new business being pursued, with slower development on larger claims.
- Unearned Premiums – increase, but remain the same in proportion to premium
- Leverage ratios – Net leverage ratios increase slightly because of the change in business model. Gross leverage ratios begin to differ materially from the net leverage ratios, and reinsurance leverage becomes important due to the purchase of reinsurance.
- Income statement – Little changed on a net basis, but over time the riskier book and changing cost of reinsurance may introduce greater volatility.

2. Provide Catastrophe Protection

This example deals with the situation where the company desires to reduce its potential loss from a catastrophic event.

Beginning Assumptions (the “Without” columns):

- ABC insurance company is in the same situation as XYZ insurance company in Exhibit 1, prior to the purchase of reinsurance. Hence, the “without” column in Exhibit 1 also applies to Exhibit 2, unless a catastrophe event occurs.
- If a cat event occurs, ABC incurs an additional $500,000 in loss, of which $50,000 is paid by the end of the year and the remainder is reserved.

Altered Assumptions (the “With” columns):

- ABC buys a catastrophe treaty on January 1st, for 5% of gross premium, that pays for losses from a single event in excess of 10% of premium. This premium is payable at the start of the year. (Note that this assumption leaves zero ceded unearned at December 31st. Ceded unearned would be greater than zero if the ceded reinsurance policy term had not yet expired.)
- This is the only reinsurance purchased by ABC.
- If a cat event occurs, ABC incurs an additional $500,000 in loss. This activates the cat treaty and the reinsurer assumes responsibility for the excess of event losses over 10% of premium, or $500,000 minus $100,000 = $400,000. Non-cat loss levels are unaffected by this event.
- Once again only 10% of the cat losses are paid by year-end, with the rest paid the following year. Note that the reinsurer does not begin paying until paid losses exceed 10% of premium, so the entire $400,000 of ceded loss is ceded reserve.
- The cat treaty has a mandatory reinstatement premium provision, with the reinstatement premium due once the cat treaty attachment is reached on a paid basis. This reinstatement premium charge is 2% of gross premium.
- The only surplus change is due to the change in underwriting results.

Analysis of impact (from Example 2)

- Surplus – Buying the cat reinsurance decreases surplus if no cat event occurs, due to the cost of reinsurance. But it can substantially mitigate the risk of significant drops in surplus if large cats occur. Note that the cost of the reinsurance in the event of a cat includes both the original premium and the reinstatement premium.
- Loss reserves – Net reserves are not impacted unless a covered cat event occurs. In that case, gross loss reserves can increase significantly for a relatively short period of time (i.e., the length of the cat payout pattern). Net reserves will return to normal levels sooner than gross reserves, as the retained portion of the cat is generally paid first before the ceded portion of the cat.
- Unearned Premiums – Little to no change (depending on the cat reinsurance policy term and accounting date), as cat reinsurance is normally a limited portion of total premium.
- Leverage ratios – If no cat event occurs, the biggest impact may be from reduced surplus in the denominator of many leverage ratios. If a cat does occur, then gross ratios and net ratios are significantly impacted without the reinsurance, while only the gross ratios are significantly impacted with the reinsurance (with the exception of ceded reinsurance leverage ratios). In general, ceded reinsurance leverage (i.e., ceded balances as a percent of surplus) can be significantly impacted in the period after a major cat, prior to the runoff of the resulting cat loss reserves.
- Income statement – Investment income is reduced by purchasing reinsurance. But underwriting income is substantially protected, with the loss limited to the original ceded premium, plus the retention and reinstatement premium if a covered cat occurs. (This assumes that the cat stays within the maximum limit of the cat reinsurance program.)

3. **Stabilize loss experience**

This example deals with the situation where loss experience may fluctuate from year to year more than management desires. Management desire may in turn be driven by capital provider demands, or management may wish to simplify the capital management process (including the determination of shareholder dividends).

**Beginning Assumptions (the “Without” columns):**

- DEF insurance company is in the same situation as XYZ insurance company in Exhibit 1, prior to the purchase of reinsurance. The “normal losses without” column reflects a “normal” loss year with a loss ratio of 75%, as per Exhibit 1.
- However, this example also recognizes the possibility that a “high” loss year may occur, with a loss ratio of 125%. If a high loss year occurs, DEF incurs an additional $500,000 in loss, of which $50,000 is paid by the end of the year and the remainder is reserved.

**Altered Assumptions (the “With” columns):**

- DEF buys an aggregate excess of loss treaty for the entire book on January 1st, for 10% of gross premium, that returns 90% of losses above a loss ratio of 100%. The reinsurance premium is payable at the start of the year. *(Note that this assumption results in zero ceded unearned at December 31st. Ceded unearned would be greater than zero if the ceded reinsurance policy term had not yet expired.)*
- This is the only reinsurance purchased by DEF.
- In the high loss example, DEF incurs an additional $500,000 in loss for a loss ratio of 125%. This activates the aggregate excess treaty and the reinsurer assumes responsibility for 90% of losses above a loss ratio of 100%, or ($1,250,000 minus $1,000,000) * 90% = $225,000.

---

1 Ceded balances are those balance sheet values arising from ceded reinsurance. In the above examples, they include ceded loss reserves and ceded unearned premiums. In a real-life example, they would also include reinsurance recoverables from amounts billed but not yet collected.
Once again only 10% of the additional losses (over and above “normal” losses) are paid by year-end, with the rest paid the following year. Note that the reinsurer does not begin paying until paid losses exceed 100% of premium, so the entire $225,000 of ceded loss is ceded reserve.

The only surplus change is due to the change in underwriting results.

**Analysis of impact (from Example 3)**

- **Surplus** – The expected value of surplus is lower after buying reinsurance, but with less period-to-period variation. The reduction is caused by the expected net cost of reinsurance. Note that while the expected impact of surplus is a reduction, the impact from year to year may vary between reductions and increases as gross losses are lower or higher than expected.

- **Loss reserves** – Stabilizing loss experience net of reinsurance generally translates into stabilizing net of reinsurance loss reserves. Gross reserves reflect the full volatility of year-to-year results, but net reserves should be smaller and more stable. (They may also be easier to estimate, as the situations that cause loss experience to fluctuate may also cause claim liability estimation to be more difficult.)

- **Unearned Premiums** – Reduced on a net basis due to the purchase of reinsurance, unless (as in our example) the reinsurance is purchased with a single effective date and the accounting date being used is the reinsurance expiration date.

- **Leverage ratios** – These ratios on a net basis should be more stable but slightly higher (due to reduced surplus), assuming there is a positive net cost of the reinsurance.

- **Income statement** – Underwriting results over time would be expected to be lower, due to the net cost of the reinsurance, and investment income would be lower. But the underwriting results from year-to-year should be more stable.

4. **Provide surplus relief**

This reinsurance deals with the situation where leverage ratios are higher than desired. Reinsurance is therefore purchased with the intent of reducing leverage ratios net of reinsurance.

**Beginning Assumptions (the “Without” column):**

- XYZ insurance company here is in the same situation as XYZ insurance company in Exhibit 1 prior to the purchase of reinsurance, except that it has fewer bonds and therefore only has $500,000 in surplus.

**Altered Assumptions (the “With” column):**

- XYZ buys reinsurance with a 50% quota share, in order to reduce its net premium to surplus and net reserves to surplus leverage ratios. This is a straight quota share, with 50% of premiums and losses ceded, with a ceding commission of 20% (consistent with the gross expense ratio).

- This is the only reinsurance purchased by XYZ.

- The altered assumptions once again reflect a steady state with consistent gross and ceded premium from year to year.

- The only surplus change is due to the change in underwriting and investment income during the year.

</tbody>
</table>

**Analysis of impact (from Example 4)**

- Surplus – Liabilities decrease because half of the losses and unearned premium are ceded, but assets decrease because of the cost of the reinsurance. The net effect in our example is a small decline in surplus, since the ceded business was profitable. This quota share reinsurance would only increase surplus if the business was being written at a loss.
- Loss reserves – Net reserves are a fixed percentage of gross reserves.
- Unearned Premiums – Net reserves are a fixed percentage of gross reserves.
- Leverage ratios – Net leverage ratios are significantly improved, although ceded reinsurance leverage ratios are significantly increased. Hence, the insurer’s solvency becomes more reliant on its reinsurers’ solvency. Note that ceding half the gross business does not halve the net leverage ratios, due to the impact of the cession on surplus. While premiums and loss reserves drop in half, surplus does not stay constant. Hence, a cession of more than 50% would be required to obtain a 50% reduction in net premium and reserve ratios to surplus.
- Income statement – Underwriting income is cut in half, and investment income is significantly reduced.

5. **Facilitate withdrawal from a market segment**

This example deals with the situation where management wants to exit a market, and is not willing to wait until the runoff of existing obligations.

**Beginning Assumptions (the “Beginning Balance” and “Without” columns):**

- XYZ insurance company here is in the same situation as XYZ insurance company in Exhibit 1 except that it stopped writing new business at the beginning of the current year. The beginning balances come from Exhibit 1, “without” column.
- Written premium for the current year therefore drops to zero. XYZ continues to earn premium, and incur losses, on business written during the prior year.
- The accounting paradigm does not recognize Deferred Acquisition Costs, so XYZ incurs a zero expense ratio on runoff earned premium.
- XYZ earns investment income on the average of beginning and ending cash and bonds.
- All loss reserves as of the beginning of the year (for events occurring in earlier years) are closed and paid at the reserve amount before the end of the year.
- Half of all losses occurring during the year are paid by the end of the year.
- Surplus changes, during the year, only due to underwriting and investment income.

**Altered Assumptions (the “With” column):**

- XYZ buys prospective reinsurance on January 1st to cede 100% of the remaining unearned premium, and all losses occurring after the beginning of the year. A ceding commission is included to cover the commission portion of the unearned premium, which XYZ paid during the previous year.
- XYZ does not buy retroactive reinsurance. Once again all loss reserves as of the beginning of the year (for events occurring in earlier years) are closed and paid by XYZ at the reserve amount before the end of the year.
- Surplus changes, during the year, only due to underwriting and investment income.

*Note: This example assumes withdrawal from all business. These results would need to be combined with results from ongoing businesses to see the combined balance sheet and income statement impact.*

Analysis of Impact (from Example 5)

- Surplus – Liabilities decline to zero as losses and unearned premium are ceded, but assets decrease because of the cost of the reinsurance. The net effect, once again, is a small decline in surplus, since the ceded business was profitable. However surplus will be less volatile if there are unexpectedly large or small losses during the runoff year.
- Loss reserves – Gross reserves are unchanged, but net reserves disappear, hence exposure to the volatility of net reserve estimates disappears.
- Unearned Premiums – Gross reserves disappear over the year as the business runs off. Net reserves disappear immediately when the unearned premium is ceded.
- Leverage ratios – Net leverage ratios are zero, hence the only remaining insurance risk is reinsurance collectability risk. Hence, surplus that was supporting the runoff business should now be free to support existing or new business, subject to supporting the residual reinsurance collectability risk.
- Income statement – Underwriting results reflect a profit because the ceding commission offsets expenses which were paid the previous year. This profit is slightly smaller than if the business had not been ceded. However the risk in the results is now greatly reduced (and limited to the risk in reinsurance collectability and in investment results).

6. **Provide underwriting guidance**

This reinsurance function arises in the situation where management wishes to enter a new market, or believes that it must be in one market to support another of its markets, but does not feel comfortable with its expertise in that new market. It therefore heavily reinsures its writings in that new market, relying on the reinsurer’s expertise in pricing and underwriting that market correctly.

No numeric example will be provided for this situation. It is conceptually equivalent to Exhibit 1 wherein reinsurance creates new business opportunities for the insurer. The impact on surplus and income will depend on the profitability and volume (after reinsurance cessions) of the new business.

THE DEVELOPMENT AND REGULATION OF CHINA’S INSURANCE MARKET: HISTORY AND PERSPECTIVES

Bingzheng Chen
Sharon Tennyson

Haizhen Zhou

ABSTRACT
China’s private insurance market has been developing rapidly since the 1980s. Regulation of the market has developed in tandem with its growth. This article provides a systematic overview of China’s insurance regulatory system and the evolving process of insurance supervision and regulation. The nature and direction of regulatory changes are evaluated in light of theories of public reform and the special character of China among developing economies.

INTRODUCTION
Although China’s modern commercial insurance market has a history of over 200 years, due to the socialist planned economy the domestic insurance industry was effectively closed from 1958 through 1979. On November 19, 1979, the People’s Bank of China held the National Insurance Working Conference in Beijing and made the decision to reestablish the domestic insurance business. From 1980 onward, China’s insurance industry has developed rapidly, becoming one of the fastest growing industries in the economic system and one whose importance continues to rise. Nominal premium income has grown at an average rate of over 30 percent per year, and China’s insurance market now ranks as the sixth largest in the world.¹

¹ Insurance premium growth calculated from China’s Insurance Yearbook. The ranking of China’s insurance market is measured by total premiums in U.S. dollars obtained from SwissRe Sigma (2012.02). That report ranked China sixth in the world, after the United States, Japan, Great Britain, France, and Germany, in 2011.
Concomitant with the development of the private insurance industry, China had to develop a modern insurance regulatory system. In 1995, the promulgation of the Insurance Law of People’s Republic of China (the Insurance Law) marked a critical step in the standardization of China’s insurance regulation. To implement the Insurance Law, the People’s Bank of China established an Insurance Division responsible for the supervision of domestic insurance companies. In 1998, insurance regulation was separated from banking and securities regulation through establishment of the China Insurance Regulatory Commission (CIRC). This marked the beginning of a comprehensive insurance regulatory system in the country.

This insurance regulatory system is still young and evolving. As the insurance market has matured, new regulatory issues have emerged and created the need for regulatory changes. Prior to 1995, the regulatory emphasis was on market behavior, with solvency supervision receiving little emphasis. With China’s entry into the World Trade Organization (WTO) and the opening of the insurance market to foreign capital in 2000, solvency regulation began to be the core focus of regulatory oversight. The modification of the Insurance Law in 2009 strengthened information disclosures, standardized contracts and procedures, and expanded the rights of consumers in order to increase the transparency of insurance transactions and enhance market functioning.

Regulatory philosophy has evolved as well. Until recently, the role of China’s insurance regulators was seen to be primarily the promotion and development of the domestic insurance industry. As problems associated with the rapid development of insurance markets have become apparent, regulatory focus has changed to that of creating a fair and orderly market environment. This change is evidenced by the remarks of Mr. Wu Dingfu—the chairman of the CIRC—in 2010, who stated that “the regulators used to be the coaches of the industry, who are concerned with building the market; but in the new era, insurance regulators should act more like judges, whose efforts should change from market construction to market supervision.”\(^1\) In keeping with this evolution, the 2009 modification to the Insurance Law and recent department rules issued by the CIRC focus on improving supervision of both solvency and market conduct. Increasingly, it is recognized that prudential supervision and consumer protections work together to maintain confidence in insurance markets and to promote the healthy development of the industry.

This article provides an account of China’s insurance market development, with special emphasis on developments in insurance law, regulation, and supervision over the past decade. The current insurance market situation and problems are discussed, and the outlook for market development and regulation in China is also considered. The next section of the article describes the development of China’s insurance market, and following that “China’s Insurance Regulatory System” describes China’s insurance regulatory system. The evolution of insurance regulation in recent years is discussed in the section “Evolution of Insurance Regulation and Supervision,” and the final section provides the authors’ perspectives on insurance regulation in China.

\(^2\) An interview of Mr. Wu Dingfu, Chairman of the CIRC. “China Finance,” 2010.06.
Market Size and Development

The private insurance market in China encompasses life insurance and property-liability insurance, with private health insurance and short-term casualty insurance counted among the life insurance sector. Initially, the private market was dominated by property insurance for business enterprises (Sun et al., 2007). Over time, life insurance markets have developed, and by 2010 the life insurance market was nearly three times as large as the property insurance market. Auto insurance contributed 77.12 percent of the total property-liability insurance premiums in 2010. In the life insurance market, participating life insurance is the most popular, contributing over 80 percent of premiums in 2010. Private health insurance is a relatively small portion of the insurance market, contributing only about 5 percent of life insurance premiums.

The Chinese government also provides a range of social insurance protections that are separate from the private insurance market. Social insurance consists of five parts: Basic Old-Age Insurance, Basic Medical Insurance, Occupational Injury Insurance, Unemployment Insurance, and Maternity Insurance. These social insurance programs are considered an important part of employees’ compensation and provide basic protections for the Chinese people. Social insurance covers a broad spectrum of the population, reaching over 1.1 billion people in 2010. The income of the social insurance fund in 2010 was 1.88 trillion yuan, and compensation paid out was 1.48 trillion yuan.

In comparison, the private insurance sector was initially much smaller but by 2010 was similar in size to the social insurance sector. Figure 1 displays annual premium revenue of the insurance industry from 1980 to 2010, along with annual insurance premium growth rates and GDP growth rates over the same period. As displayed in the figure, nominal insurance premiums increased from 460 million yuan in 1980 to 1.45 trillion yuan in 2010, an average annual premium growth rate of over 30 percent, compared to a nominal GDP growth rate of 16 percent.

Measures of insurance market maturity have grown along with the rapid growth in the market. As depicted in Figure 2, China’s insurance density, measured as insurance premiums per capita, rose from less than 1 yuan in 1980 to over 1,000 yuan ($158.50 in U.S. dollars) in 2010. Insurance penetration, measured as premiums relative to GDP, increased from 0.1 percent in 1980 to 3.65 percent in 2010.

Nonetheless, China’s insurance market is far from mature when compared to other countries. China’s insurance penetration and insurance density relative to other world

---

3 We provide only a brief overview of China’s insurance market development for background purposes; see Sun et al. (2007) for a more detailed discussion of the development and structure of the insurance industry.

4 Data are from China’s Insurance Yearbook 2011.

5 There is also a Public Reserve Fund for Housing. The five components of the social insurance program and the housing reserve fund are together described as the “Five Insurances and One Fund” and constitute the social safety net provided to workers.

6 Data on social insurance are from the Statistical Bulletin of human resources and social security development (2010); see http://www.molss.gov.cn/gb/zwxx/2011-05/24/content_391125.htm.

economies is displayed in Figure 3. The figure shows that measures of insurance density and insurance penetration are far below worldwide averages ($627.30 for insurance density and 6.90 percent for insurance penetration in 2010, respectively). China ranked 61st in insurance density and 39th in insurance penetration among world economies in 2010.

Insurance Market Structure

The number of insurance sellers in China has increased along with the size of the private insurance market. In 1980, the market was served only by the People’s Insurance Company of China (PICC), which was directly controlled by the government (Sun et al., 2007). In 1996, only 21 insurance firms operated in the market. By 2010, 126 insurance firms were doing business in China. Table 1 reports the number of insurance companies, subsidiaries and branch offices, and the Herfindahl–Hirschman Index (HHI) of competitiveness for life and nonlife insurance for selected years. The data show that the competitiveness of the market has increased with the growing numbers of market players. Nonetheless, the markets remain relatively concentrated. In 2010, the nonlife insurance HHI was 1850 and the HHI for life insurance was 1800. To provide a benchmark, U.S. Department of Justice merger guidelines categorize markets with HHI greater than 1800 as “concentrated” (DOJ/FTC, 1997).

Some of the growth in number of firms is due to the entry of foreign insurers into China. As part of China’s entry into the WTO in 2001, China’s insurance market was among the very first industries opened to foreign investors. Figure 4 shows the entry of foreign insurers in each year 1992–2010. Foreign entry accelerated after 2001, especially the entry

### Figure 4
Entry of Foreign Insurers Into China’s Life and Nonlife Insurance Markets

This may be due to the greater differences in China’s regulation of foreign and domestic nonlife insurers as compared to regulations for foreign and domestic life insurers. For example, until 2004 foreign nonlife insurers were forced to operate as branches rather than subsidiaries (Zhao, 2009), and foreign insurers are still excluded from offering compulsory insurances such as automobile liability coverage (Huang and Query, 2007). Nonetheless, China’s regulations are more restrictive for foreign insurers than for domestic insurers, even in life insurance. This difference may be an important determining factor in insurance market structure, competition, and efficiency (Zhao, 2009).
The Structure of China’s Insurance Regulatory System

As discussed by Zheng (2011), insurance regulation in China is governed by laws (the Insurance Law and other laws) passed by the National People’s Congress (NPC), administrative regulations developed by the State Council, and department rules issued by the CIRC. Industry self-regulation occurs through an insurance industry association, and less formally, legal supervision occurs through the actions of the courts, and social supervision through the media and private citizens. Figure 5 displays the relationships between regulatory governance structures, and the important functions of the regulatory institutions are described below.

The NPC and the Insurance Law

As defined in China’s Constitution, the NPC is the most powerful authority in the country: it determines national priorities, names the leaders of governmental institutions, and passes laws. The Insurance Law, the first law put into place regarding the operation

and supervision of insurance markets, was approved and implemented in 1995. With 152 articles in 8 chapters, this law provided detailed and systematic rules for insurance contracts, insurance companies, insurance activities, and insurance supervision in China.

Table 2 chronicles the development of the Insurance Law over time. In 2002, the NPC approved the first modification of the Insurance Law. Modifications were aimed primarily at fulfilling China’s commitment of opening its insurance market upon joining the WTO. Almost immediately (beginning in October 2004), work began on developing yet more substantial revisions to the Insurance Law. This second modification expanded the number of provisions in the law from 158 to 187, and revised or replaced nearly every provision in the earlier law. This new Insurance Law came into effect in October 2009, and is more complete on important facets of industry oversight such as legal standards in the insurance contract, institutional arrangements among insurance market participants, and insurance supervision. Notably, the new law increases the CIRC’s enforcement and supervisory authority.

The State Council

The State Council is the representative of NPC and performs the executive functions of government. Administrative regulations are developed by the State Council as authorized by the constitution and laws of the Republic. The State Council delegates active regulatory oversight to the specific regulatory departments of each sector of the economy. As a result, the CIRC performs most of the active regulation of the insurance sector, and NPC administrative regulations are established only for large issues or issues that affect more than just the insurance sector. Examples include regulations regarding foreign insurers (Foreign Insurance Administrative Regulation, 2001) and regulations regarding supervision are also regulated by other related legal norms. For example, as in many other countries, contract law can be applied to regulate the insurance contract and corporate law can put constraints on insurance companies. Laws regarding government administrative review, administrative penalty, or administrative licensing apply to the activities of insurance supervisors.
liability for motor vehicle accidents (Administrative Regulation on Compulsory Motor Vehicle Accident Liability Insurance, 2006).

The CIRC

The CIRC is the primary regulator of private insurance in China, conducting direct supervision of the insurance industry according to the authority granted to it by the State Council. The CIRC is considered to be a functional department of the State Council. All functional departments of the State Council, including the CIRC, have independent rule-making authority and CIRC has been very active in rule making. While administrative regulations of the State Council take legal precedence over department rules, CIRC usually works in cooperation with the State Council to develop those regulations. For example, CIRC worked with the State Council on the administrative regulations regarding foreign insurance companies and motor vehicle insurance regulations that were mentioned above.

CIRC shoulders much of the insurance regulatory duties and its regulatory independence and impact have increased over time. The regulatory responsibilities of CIRC are broadly defined and are comparable to those of insurance regulators in many countries. Table 3 compares CIRC responsibilities with those of insurance regulators in 78 countries who reported information to the Insurance Laws Database of International Association of Insurance Supervisors (IAIS) in 2009; the comparison shows that CIRC performs the usual set of regulatory functions.

Consistent with its independence and broad authority, CIRC has been active in rule making since its establishment. Figure 6 shows CIRC rule-making activity by year for 2002–2010; during that period CIRC promulgated 56 rules covering wide-ranging aspects of insurance operations.

Within the CIRC itself there are currently 16 operational departments, which can be divided into market regulatory departments (Life Insurance Department, P&C Insurance Department, Insurance Intermediary Department, etc.) and functional departments (Development and Reform Department, International Department, Statistics Department, etc.). To improve local enforcement, the CIRC has also established 35 branch offices (“dispatched institutions”) in 22 provinces, 4 municipalities, 4 autonomous regions, and 5 cities throughout China. Since 2010, the CIRC has been building regulatory bureaus in secondary cities. So far there are five such bureaus in the cities of Suzhou, Tangshan, Yantai, Wenzhou, and Shantou.

The central departments of CIRC are responsible for regulatory policymaking, and industry-level issues such as licensing of insurance companies are handled by these departments. The branch offices of CIRC do not have rule-making authority but are responsible for and largely determine the local enforcement of insurance regulations. Due to differences in enforcement activities, Zhao (2009) emphasizes that there are many regional differences in insurance regulation and supervision in China, with the more

developed provinces in the East taking the lead in modernizing insurance regulatory practices.

Industry Self-Regulation

The industry’s self-regulatory organization is the Insurance Association of China (IAC), founded March 12, 2001. The Association is authorized by the CIRC and registered by the National Ministry of Civil Affairs as the self-regulatory organization of the Chinese insurance industry. It is a voluntary, not-for-profit organization. At present the IAC has 176 members, including 105 insurance companies, 36 insurance intermediary firms, and 35 local insurance industry associations.

In addition to the IAC, there are also self-disciplinary “Intermediary Associations” for insurance intermediaries on the provincial and city levels (Zhao, 2009). First established in Shenzhen in 2004, an Intermediary Association takes responsibility for setting up self-disciplinary standards for its members. Although usually supervised by local CIRC
branch offices, these local associations are not officially recognized by the Insurance Law.

Self-regulatory organizations strengthen self-discipline within an industry by putting constraints on the business activities of its members. The IAC regards this as its primary mission and declares the following specific aims:

- To constrain unfair activities by formulating industry standards and professional industry guidance.
- To promote honesty in professional ethics and to establish a complete system of accountability in the insurance industry.
- To strengthen the self-discipline management of insurance professionals and intermediary agencies by supervising business activities and enforcing compliance through penalties.

In developed market economies, industry self-regulatory organizations often play a very important role in promoting market self-discipline. These organizations provide strong professional services and education, participate in the development of legislation, formulate industry standards of conduct, and enforce adherence to laws, regulations,
and industry standards. In contrast, the IAC has a very short history, is relatively small in size, and lacks real independence from the CIRC. For example, the IAC has no enforcement authority, but may only warn, condemn publicly, or ask the CIRC to impose a punishment.\textsuperscript{12} Thus, in China the role of industry self-regulation is less important.

Legal and Social Supervision

The Supreme People’s Court serves to provide judicial interpretation of laws and has issued a number of rulings regarding application of the Insurance Law (Zheng, 2011). One important example is a decision in 2004 that established benchmarks for compensating personal injury claims in automobile accidents (Huang and Query, 2007). However, the role of China’s judicial system in enforcing insurance contracts and promoting market discipline is relatively undeveloped and is still evolving. The courts in China are not independent of the state and are funded and managed by local governments. China does not have a strong history of commerce being governed by contract and liability norms, and there is not a well-developed case law system (van Rooij, 2011). Lack of well-trained judges in insurance law and inconsistency of judgments across similar cases seem to be obstacles in efficient judicial supervision.

Less formal aspects of social supervision of industries include attention from consumers, the news media, and public opinion. In recent years, insurance regulators have begun to pay more attention to this mechanism of disciplining the insurance market. For example, in 2009 the CIRC issued opinions on professional norms for insurance regulators and insurance professionals, and emphasized that insurance consumers—not just regulators, companies, and intermediaries—should become informed about them in order to strengthen supervision by society.\textsuperscript{13}

Nonetheless, effective social supervision is difficult in an area such as insurance due to its complexity and the lack of easily visible signs of regulatory violations. van Rooij (2011) argues that “people’s regulation” is most effective when the regulated behavior is simple and violations are easily visible. Moreover, behavioral norms for insurance dealings are not well developed on the customer side of the market either. Fraud in insurance applications, and in insurance claiming by consumers and by consumers in collusion with agents, is perceived to be a large problem (Huang and Query, 2007; Zhao, 2009). For example, news articles report that more than 70 insurance fraud cases were detected in Jiangsu Province alone since 2008, resulting in over 100 million yuan in losses to insurance companies.\textsuperscript{14}

**Evolution of Insurance Regulation and Supervision**

The evolution of China’s approaches to insurance supervision and regulation has been shaped by many forces, including the progress of domestic insurance markets, the increasing international connectedness of the markets, and international developments in insurance supervision. Entry into the WTO in 2001 marked a new era not just for China’s insurance industry but also for its regulation and supervision.

\textsuperscript{12} The information is taken from the Constitution of the Insurance Association of China (2001).
\textsuperscript{14} In response, China’s first Anti-Fraud Center was established in Jiangsu Province in 2011.
Opening up of the market strengthened connections and cooperation with international organizations and other insurance regulators. In many areas, the CIRC has been active in monitoring and adopting the common global standards promulgated by such bodies as the IAIS and the European Union (EU). In 2005 the IAIS articulated the “three pillars” of insurance supervision as consisting of regulation of corporate governance structure, regulation of market behavior, and regulation of solvency. China adopted the “three pillars” as the basis for insurance supervision in 2006. China is also closely following the implementation of Solvency II in Europe, and studying the management of systemic risk as an important part of future insurance regulation.

More generally, over the past decade China has modernized its insurance regulation and supervision in a variety of dimensions, including both regulatory process and content. Some of the major developments are described below.

Asset Management Regulation

Asset management in insurance companies has traditionally been strictly regulated in China. The Insurance Law of 1995 restricted insurance companies’ assets to be invested only in bank deposits, government bonds, corporate bonds, and other funds stipulated by the State Council. The restrictions have been relaxed gradually over time, beginning in 1998 when a certain proportion of insurance assets were permitted to be invested in securities. During the succeeding years, the nature of allowable investments has been gradually expanded. Nonetheless, asset management regulations remain restrictive in comparison to those in other countries.

Table 4 presents a comparison of investment limitations for China’s insurance companies relative to other jurisdictions in 2010. Chinese insurance companies face significant restrictions on investing in risky assets, with no more than 20 percent of assets permitted to be invested in stocks or in corporate bonds, respectively, and no more than 10 percent of assets permitted to be invested in real estate and mortgages. Overall, nearly half of insurance company assets must be invested in government bonds and bank deposits. China’s Central Bank reports that in 2011, 32 percent of insurance companies’ assets were invested in bank deposits, while bonds (both government and corporate) contributed 47 percent.

Solvency Regulation and Supervision

The Insurance Law of 1995 provided only basic guidelines regarding minimum solvency requirements for insurance companies. The first comprehensive and systematic regulation regarding solvency supervision came about in January 2001 in conjunction with requirements for China’s entry into the WTO. This regulation developed a ratio-based solvency monitoring system, specifying the calculation of ratios, and standards for recognizing assets. It also established measures for dealing with distressed or insolvent insurance companies.

Source: IAIS Insurance Laws Database, the Temporary Administrative Measures of Utilization of Insurance Capital by CIRC.

The Insurance Law modification of 2002 led to additional strengthening of this system by revising the solvency ratios and requiring insurers to submit periodic reports on the solvency measures. CIRC started to build a modern solvency regulation system in 2003. With the establishment of the China Insurance Solvency Standards Committee in 2007 and the first complete solvency regulation provision in 2008, CIRC established a dynamic risk-based solvency regulatory framework consistent with international standards, indicating the establishment of “the first-generation insurance solvency regulation system in China.” After the financial crisis, and in the wake of the evolution of the global financial regulatory system, CIRC began development of a new solvency monitoring system better suited to the new market environment and global situation. CIRC issued a planning document in 2012 that announced plans to draft a “second-generation system” by the end of 2014.

The growing concern with solvency regulation from the CIRC has led directly to an increase in required capital injections from insurance shareholders. Table 5 shows the number of insurance companies whose shareholders injected capital and the total amount injected (RMB yuan), in each year 2005 through 2011. Even prior to the global financial

---

19 See http://www.circ.gov.cn/web/site0/tab4566/i203919.htm.
crisis, capital injections to life insurers were substantial in some years, and the number and amount of capital injections increased dramatically following the crisis. In 2011, 14 life insurers and 5 nonlife insurers required capital injections totaling nearly 4 billion (RMB).

On-site and off-site examinations (inspection of insurance company statements and materials) are important supervisory methods used by insurance regulators worldwide (e.g., Klein and Schacht, 2001) and are an important tool for China’s insurance regulators. In the past decade, the CIRC has expanded requirements for insurance company reporting, broadened the focus of off-site examinations, and improved its risk-monitoring measures. It has also inaugurated a program of on-site spot-inspections to directly examine the operations, activities, and financial situations of insurance companies.

The CIRC carried out nationwide spot-inspections for the first time in 2006. These inspections were broadly focused and included examination for irregular operations in auto insurance and large property insurance, irregularities in fee collections from the bank and postal agency life insurance business, the accuracy of financial data, other business fraud, and problems regarding insurance capital utilization and statistical data. The use of on-site examinations has continued as an important focus of supervision since that time. By 2008 the CIRC sent out 2,052 examination groups to carry out spot-inspection of six insurance companies, 1,407 insurance branches, and 740 insurance intermediaries in the property–liability and life insurance sectors.\(^{20}\)

The Insurance Protection Fund
China established an insurance guaranty fund (the Insurance Protection Fund, IPF) in January 2005. The fund was initially managed by CIRC under the oversight of an IPF Council consisting of representatives of insurance companies, the Legislative Affairs

Office of the State Council, Ministry of Finance, the People’s Bank of China, and others. In October 2007, responsibility was transferred to a new entity, the China Insurance Protection Fund Ltd. Co. New administrative regulations were put into place in September 2008, which established rules for the business operations, governance structure, financing, and information-sharing activities of the Protection Fund management company.

The IPF provides full compensation of losses up to 50,000 yuan for policyholders of insolvent nonlife insurers; individual policyholders receive 90 percent of losses over 50,000 yuan and institutional policyholders receive 80 percent of losses. The policies of insolvent life insurers are transferred to another life insurer and the accepting insurance companies receive compensation from the fund for losses associated with the transferred policies. Insurer compensation is limited to 90 percent of losses for individual policies and 80 percent of losses for institutional policies.

There have been no instances of bankruptcies for insurance companies in China. However, the IPF has injected capital into two companies in financial distress. Xinhua Life Insurance Company, the fourth largest life insurance company in China at that time, reported that its CEO misappropriated company assets in 2007. To protect the policyholders and help the company through the distress, the IPF began purchasing company shares. The IPF initially purchased 22.53 percent of the company’s shares by injecting over 1.619 billion yuan into the company; by 2008 the IPF held 38.82 percent of shares and was the largest single shareholder of the company. In November 2009, the IPF transferred its total shareholding of Xinhua Life to Central Huijin Investment Ltd., a state-owned investment company.

The second IPF rescue operation occurred in 2011 when China United Insurance Company, an insurance group with a long history, fell into financial distress due to improper management. The IPF purchased 57.43 percent of the company’s shares in November 2011 and injected another 6 billion RMB in March 2012, which left the IPF with a 91.49 percent stake in the company. After receiving a further 7.81 billion RMB in capital from another large investor in October 2012, China United Insurance moved beyond the insolvency problem. The IPF remains the second largest shareholder in the company, but is now looking for a means of exit.

Insurance Rate Regulation
In the initial phase of the private insurance market, in which there was only a single government-owned insurer, government-set rates were quite natural. At that time, private insurance was more like a public service provided by the government’s agent, the People’s Insurance Group. As new entrants led to competition in the market, the

---

22 Xinhua Life insurance company reported 26 billion RMB premium revenue in 2006, which made it the fourth largest life insurance company in China. Data are from CIRC’s statistics.
government has experimented with relaxation of rate regulation. Currently, however, most insurance product lines are still under strict rate regulation.\textsuperscript{25}

There are two basic objectives that may be pursued in regulated insurance rates: regulations can try to control the upper limit of premium rates to prevent monopoly pricing, or regulations can set lower limits on premium rates to prevent vicious price competition, which could lead to insolvencies. In the Chinese insurance market, due to concerns that insurers will blindly pursue market share in selling relatively homogeneous products, insurance rate regulation has primarily focused on the second objective.

In some countries, insurance rate regulation may also place limits on the differences in premiums paid by different groups of consumers, in an attempt to improve insurance affordability for high-risk or low-income consumers. In China, rate regulation serves this purpose for certain kinds of insurance, such as agricultural insurance, but is not a focus of rate regulation in general.

Rate regulation of private passenger automobile insurance provides a useful illustration of China’s experiences.\textsuperscript{26} As one of the most important nonlife insurance products, automobile insurance market remains the most stringently rate-regulated line. However, there have been three waves of market-oriented rate regulation reforms since 1980:

- **Wave 1 (1988–1993)** was driven by the entry of new market players when the government decided to expand the set of insurers to eliminate the monopoly held by the People’s Insurance Group. Along with the entry of China Ping’an Insurance Group and several other insurance companies, rate regulation was relaxed from government rate setting to government prior approval of company rates. With rate flexibility allowed, and facing an entrenched monopoly, the new market players engaged in premium cutting to pursue greater market shares. This period of market-set rates was thought to be a failure and was ended by the regulator (the Central Bank) in 1993, and competition in products and rates was again eliminated. All insurers were required to issue the same contract form, and government-set rates were established for each region of the country. All provisions regarding auto insurance contracts and rates were controlled by the regulator, leaving no room for differentiation across insurers.

- **Wave 2 (2001–2006)** occurred after the establishment of the CIRC and China’s entry into the WTO. Although the WTO did not explicitly require relaxation of rate regulation, it nonetheless put pressure on China to modernize insurance regulation. The CIRC started to relax rate regulation by allowing insurers to implement their own insurance product provisions and rates. This process eventually failed again due to underpricing problems. In response, CIRC set up three universal contract forms (offering different combinations of coverage) along with premium standards

\textsuperscript{25} According to Administrative Measures for Life Insurance Provisions and Premium Rates (2011) and Administrative Measures for Non-Life Insurance Provisions and Premium Rates (2010), the premium rates of all major insurance product lines must be approved by CIRC before the companies want to use them.

\textsuperscript{26} The rate regulation discussed here does not apply to the Compulsory Third Party Motor Vehicle Liability Insurance, whose rates remain set by the CIRC.
for each form. These three contract forms were the only forms that auto insurers could offer.\textsuperscript{27}

- Wave 3 (2011–) began in 2011. This time, the CIRC put certain solvency requirements on insurers who wish to apply for flexible rate-making authority.\textsuperscript{28} These requirements are an attempt to prevent insurers with poor financial and solvency performance from engaging in excessive price competition, and thereby to ensure that competitive rate setting will not lead to unstable markets. Insurers who are granted flexible rate-making authority must report contract provisions and rates to CIRC, including basic assumptions in making the rates and actuarial analysis supporting the rate structure.

Disclosure and Consumer Protection

Consumer protection has attracted increasing attention in insurance regulation. Irregularities in insurance contract fulfillment have been a persistent problem for consumers and have hindered the expansion of the insurance market. Numerous (unsubstantiated) reports by consumers on social media sites describe disputes with insurers in areas including contract features, underwriting decisions, and claims. According to a survey of insurance consumers conducted by Shaanxi Consumers Association in 2010,\textsuperscript{29} difficulty in claim filing was thought to be the most important concern for the consumers when considering purchasing insurance (49.3 percent). More substantiated reports of consumers’ problems with insurers can be found in the Consumer Education section of CIRC’s website, which provides examples of selected cases of irregular operations encountered by regulators.\textsuperscript{30}

The most significant modification in the new Insurance Law of 2009 was its increased attention to consumer protections, demonstrating the determination of regulators to improve the contracting environment. Observers have noted that the law will put heavy pressures on insurance companies in the short run, due to the substantial new restrictions on market conduct and increased disclosure requirements (Jin, 2009). However, these same observers note that the strengthening of regulation and market transparency should improve the health of the market in the long run (Jin, 2009; Hu, 2009).

The Insurance Law requires formatted provisions in insurance contracts to protect consumers from overlooking important terms and conditions. The rights of insurers to terminate contracts are restricted to situations when the insurer can demonstrate that the insured engaged in improper or fraudulent behavior. Procedures and time limits for claims payment (within 10 days of coming to agreement) were also established in the law.\textsuperscript{31}

In the past 3 years, the CIRC has issued major new regulations regarding disclosure requirements for insurance companies. In 2010, seven specific areas in which

\begin{footnotesize}
\begin{enumerate}
\item See http://www.circ.gov.cn/web/site47/tab4339/.
\item Li and Chongmiao (2009) discuss nine areas in which the law increases consumer protections.
\end{enumerate}
\end{footnotesize}
insurance companies must release information to the public were identified.\textsuperscript{32} Companies are required to report the relevant information on their website and in a newspaper designated by the CIRC. Reports must be released annually, and the reports of at least the most recent 5 years must be maintained on the company website.

Regulation of Foreign Insurers

Entry into the WTO committed the Chinese government to open its insurance markets to foreign competitors. Since that time, restrictions on location, products, reinsurance, ownership, and other facets of insurance company operations have been gradually loosened. Although insurance should be considered one of the industries that is most open to foreign investors, there are still some very crucial restrictions on foreign insurers.

For example, foreign nonlife insurers are not allowed to underwrite third-party liability insurance for motor vehicles, which has hindered development of their motor vehicles insurance products. Also, foreign investors are still constrained to holding no more than 50 percent of a life insurer’s shares. The result is that 10 years after the opening up of the market, foreign insurers are still “struggling” in China’s insurance market. The market shares of foreign insurers in China are only about 1 percent in the nonlife sector and 5 percent in the life sector, far below that in other countries’ insurance markets.\textsuperscript{33} The discriminatory regulation is at least one of the causes of this situation.

\textbf{Perspectives on Insurance Regulation in China}

As the preceding discussion makes clear, China’s insurance regulatory system developed rapidly but unevenly, with some areas receiving inadequate regulation and others being overregulated. The speed and direction of regulatory reforms has responded to these imbalances and to developing economic and market conditions in the industry. Along with the blind pursuit of market expansion and development came a number of associated market problems, and this coupled with changes in the international insurance market after the global financial crisis have modified the development objectives for China’s insurance industry. In recent years, the financial strength and health of the industry has gained in emphasis, and the need for consumer protections has attracted growing attention.

It is by now well recognized in comparative political and economic analysis that institutional history and context are important determinants of the evolution of institutions in response to pressures for change. With this in mind, the path of China’s insurance regulatory development must be viewed in the context of China’s more general transition from a planned economy to a socialist market economy. Much has been written about China’s unique approach to transition, which included gradual and pragmatic reforms and development of private enterprises operating in parallel with state-owned enterprises (Qian, 1999, 2000; Ahrens, 2007). This approach characterizes the transition in the insurance sector as well as in the economy overall.

\textsuperscript{33} The premium data are from CIRC’s website, and market share is calculated by the authors. For a more detailed analysis of this issue, see Chen et al. (2012).
In evaluating changes in public management in 10 countries since 1980, Pollitt and Bouckaert (2000) relate a general model of public management reform, in which they argue that public management reforms are driven by a variety of external forces but are shaped by the political and administrative systems within a country. According to these authors, the political system shapes the perceptions of what evolution is desirable and the administrative system determines what is feasible; together, these determine the speed and direction of reforms. We apply this model more narrowly to the evolution of China’s insurance regulatory system, where “evolution” is used to refer to the broad scope of changes including the drift in regulatory philosophy, the modification of the Insurance Law, the increasing focus on solvency and consumer protection, and greater cooperation with international markets and organizations. Figure 7 depicts the interrelationships between the various forces at work in China’s insurance regulatory evolution.

China’s overall stage of economic development also influences the nature and evolution of insurance regulation. A growing literature considers the special problems that governments in developing countries face when regulating private industries (Laffont,
The primary thesis of this literature is that certain institutional weaknesses in developing countries make effective regulation more difficult and should be accounted for when designing the regulatory system. As outlined by Estache and Lewis (2009), regulators in developing countries are usually subject to one or more of the following institutional weaknesses: limited regulatory capacity, limited commitment, limited accountability, and limited fiscal efficiency.

Qian (1999) rightly notes, however, that on the one hand China is a developing country and on the other hand China is transitioning from a centrally planned economy. This creates special characteristics which must be accounted for in understanding the development of China’s insurance regulation. As indicated by van Rooij (2011), China’s regulatory capacity and fiscal efficiency are stronger than in many other countries due to its long history of state administration.

China’s current market economic system has evolved from a strong planned economy, which, together with the socialistic political system, leaves China with strong bureaucratic actors in almost every economic field. This was initially manifested as strong “top-down” administrative interference in market operations. A perfect example is the initial supervisory priority placed on expanding the market and accelerating its development when the insurance industry was first developing. The strong “top-down” bureaucratic system caused severe neglect of consumer protection in the industry. Through incremental change this has gradually been transformed into promoting the healthy development of the market, as evidenced by the increasing attention to consumer protection in the Insurance Law of 2009.

However, the lack of effective constraints on government actions makes limited commitment and limited accountability issues significant problems in China. As described by Qian (2002), China’s 30-year economic growth might be characterized as a miracle given the absence of many conventional institutions such as rule of law and secure private property rights. In the insurance industry, high entry barriers and discriminatory treatment of foreign and privately owned companies (compared to the state-owned companies) have received frequent criticism. How such problems will affect the future development of the insurance market must be considered by anyone wanting to make predictions about these issues.

Nonetheless, regulatory process is gradually evolving along with the continual efforts to modernize regulatory rules and procedures to accord with international standards. Compared to the 2002 Insurance Law modification, which was approved in a single process by the Standing Committee of the Ninth NPC, the Insurance Law of 2009 went through a more rigorous legislative process. CIRC started the modification process as early as 2004, and the first draft approved by the State Council in August 2008 went to the Standing Committee of the Eleventh NPC. After that, three rounds of reviews were

---

34 Although this literature has considered almost exclusively the regulation of infrastructure monopolies such as utilities, some principles may be extended to regulation of financial services such as insurance.

35 Recent investigative journalism reported in the New York Times offers a fascinating story of asymmetric treatment and lack of regulatory accountability within the insurance regulatory system as recently as 10 years ago (Barboza, 2012a, 2012b).
adopted before the final version was approved, with more than 60 different entities or
organizations involved. Opinions from consumers were collected through a government
website during the second round, which contributed more ideas on consumer protection
provisions in the new law.36 This legislative process allowed the interests of many more
stakeholders to be considered in developing the law, and wider stakeholder engagement
and involvement are important means by which accountability can be increased.

The evolution of China’s insurance regulation outlined in this article reflects remarkable
progress in institutional development over a short period of time. Rapid development
of the market due to global and domestic economic forces has greatly compressed the
timeframe for development of regulatory institutions, providing a fascinating case study
and a useful example for emerging industries within China and around the developing
world.

Determining eligibility of the premium allocation approach under IFRS 17 for Non-Life insurers
Executive summary
Upon adoption of IFRS 17 *Insurance Contracts* (IFRS 17 or the Standard), many Non-Life (or Property & Casualty) insurers are seeking to manage costs and operational complexity and limit changes from their current accounting approach. As a result, many will seek to use the Premium Allocation Approach (PAA) for either all or, as much of their business as possible, as it is easier to apply and more aligned to the current accounting and reporting than the General Measurement Model in IFRS 17 (also known as “Building Block Approach” or “BBA”).

As there are some restrictions to the use of the PAA, this paper explains how to assess the PAA eligibility requirements in practice and the steps that can be taken in order to determine how much of the business is eligible for the PAA. In many cases, Non-Life insurers may find that the vast majority of their business can adopt the PAA. However, if not all contracts of an entity can be accounted for under the PAA, then the entity needs to apply the BBA to those contracts.

**Why PAA for Non-Life insurers?**

Under the PAA, the valuation of the unearned portion of the liability (referred to as the liability for remaining coverage (LFRC) in IFRS 17) can be seen as being similar to a calculation under current accounting of (i) the unearned premium reserve less (ii) deferred acquisition costs less (iii) premium receivables (plus (iv) any additional unexpired risk reserve for unprofitable business).

The liability for incurred claims (LFIC) represents the estimate of amounts due to policyholders for claims incurred from earned portions of the liability. This is calculated based on estimates of future cash flows adjusted for the time value of money plus a risk adjustment for non-financial risk.

The PAA is potentially attractive for Non-Life insurers as it is simpler to calculate than the BBA. The PAA is more familiar as it can be more readily compared with the current accounting approaches, although there are some differences in measurement, particularly in relation to LFIC. In addition, and consistent with the simplified nature of the PAA, the disclosure requirements are expected to be less onerous under the PAA compared to the BBA.

It is also useful as it may be more comparable to peers who do not adopt IFRS 17 (particularly important in the Specialty market where many insurers report under U.S. GAAP\(^1\)).

---

1. Although U.S. GAAP uses the same fundamental mechanics of an allocation of the total premium, differences exist between the accounting model for short-duration contracts under U.S. GAAP and the PAA under IFRS 17.
Which contracts qualify for the PAA?

There are criteria in IFRS 17 for determining whether the PAA can be applied to a group of (re)insurance contracts (group). A group is eligible for the PAA if either:

(a) the coverage period of each contract in that group is one year or less, or

(b) if using the PAA would produce a measurement of the LFRC for the group that would not differ materially from the one that would be produced applying the BBA.

As a result, a Non-Life insurer that only writes contracts that are one year or less in coverage period can use the PAA without any further work needed to demonstrate eligibility.

However, many insurers will write at least some types of contracts that are longer than one year in coverage period. This raises the practical question of how an insurer can determine which contracts that are longer than one year can be accounted for under the PAA by applying condition (b) above, as this requires some form of “materiality test” to be passed.

This paper discusses how this materiality test could be applied in determining the PAA eligibility of a group. Materiality in this context should be as defined by IAS 1 Presentation of Financial Statements (IAS 1) and IAS 8 Accounting Policies, Changes in Accounting Estimates and Errors (IAS 8). In addition to the general requirements of IAS 1 and IAS 8, there are specific materiality requirements in IFRS 17. Eligibility for the application of the PAA must be assessed for each group of insurance contracts and therefore materiality should be considered at the group level. For groups which contain any contract with a coverage period longer than one year, PAA eligibility is determined by applying a range of future scenarios that an entity would reasonably expect, within the context of the particular group. The carrying amount of the LFRC at each reporting date under those scenarios is compared between the PAA and BBA. When any difference between the carrying amount of the group’s LFRC between the PAA and BBA at each reporting date in all scenarios is below a specified threshold of materiality, then the group is eligible for the PAA. This materiality threshold should be designed to assess if the carrying amount of the LFRC at each reporting date under the PAA is not materially different from the carrying amount of the LFRC under the BBA for the particular group.

---

2 IFRS 17.53
Main sources of difference between the PAA and BBA
Under IFRS 17, insurance liabilities are split into two parts: LFIC and LFRC. The components for each part are illustrated in the diagram below:

In nearly all situations the LFIC is the same between the PAA and BBA. The criteria for PAA eligibility only depend on measurement of the LFRC and the coverage period of the underlying contracts, so the measurement of the LFIC is not further discussed in this paper.

There are a number of situations in which the PAA and BBA can produce different measurements for the LFRC, which could impact on the eligibility of contracts for applying the PAA. In the sections below we discuss some of the most prominent sources of difference and provide illustrative examples where relevant. They are:

(a) Changing expectations of profitability for the remaining coverage period (e.g., due to changes in claims expectation)

(b) Changing market yield curves

(c) Earnings patterns which are influenced by the pattern of claim events arising (e.g., seasonality of catastrophe exposures)

The above list of sources of differences is not exhaustive; various other factors could contribute to differences between the PAA and BBA outcomes. In addition, the accounting simplifications available under the PAA of immediately expensing the acquisition cash flows and/or not accreting interest under the PAA if there is no significant financing component, would also have an impact on differences in the LFRC between the PAA and BBA, although these simplifications would not impact the outcome of the PAA eligibility assessment. For illustrative purposes, these differences have been ignored in the simplified examples provided below.

---

3 Under the PAA, when the cash flows are expected to be paid or received in one year or less from the date the claims are incurred, then the entity may choose not to adjust those cash flows for the time value of money. This could cause a difference in LFIC under the PAA and BBA but would not affect the comparison of the LFRC between the two models.

4 IFRS 17.59(a)

5 IFRS 17.56
Changing expectations of profitability for the remaining coverage

When the expectation of the remaining profitability changes during the coverage period of a group, so that it is still profitable, the results can differ under the PAA and BBA.

In this situation, the PAA would not recognise this improvement or deterioration in profitability until the exposure is earned (i.e., the insurance revenue for the cover and the related incurred claims and expenses are recorded in profit or loss). Under the BBA, however, per paragraph 44 of the Standard, the CSM would be adjusted for this change in profitability first before the proportion of CSM that relates to the current period being recognised as insurance revenue.

This is due to IASB’s conclusion that allocating the amount of CSM adjusted for the most up-to-date assumptions provides the most relevant information about the profit earned from service provided in the period and the profit to be earned in the future from future service⁶. As such, the BBA may already recognise a portion of this change in expectations through the release of the CSM.

Example 1 shows a 2-year contract which is expected to be profitable at inception, but which has a change in estimate for the remaining profitability at the end of year 1 due to a change in expected future claims, with all other factors remaining equal. It shows how the LFRC changes under both the PAA and BBA.

Example 1: BBA and PAA LFRC after a change of expectations on future profitability

<table>

<td>Loss component</td>
<td></td>
</tr>
</tbody>
</table>

⁶ IFRS 17.BC279(b).
⁷ In this scenario, the LFRC under the BBA does also include a loss component.
We note the following from this example:

1. At inception the PAA and BBA give the same LFRC (this will always be the case).
2. If the estimate of future claims experience is unchanged at the end of the first reporting period, then the PAA and BBA will produce the same LFRC (the "Base Case").
3. Where expected future claims increase, the BBA gives a higher estimate of LFRC (and vice versa with a reduction in expected future claims).
4. Where the increase in expected future claims is larger than the remaining CSM, the BBA and PAA give the same LFRC (the CSM goes to zero under the BBA and under the PAA, a loss component liability is set up using the IFRS 17 fulfilment cash flows (FCF) under the BBA).

The significance of these differences will vary depending on how likely it is that the expected profitability of the remaining coverage might change and how much it may change.

The change in the expectations of future profitability is more likely to make an impact in the following situations:
- Longer duration contracts (more chance of a change happening)
- Contracts where the expected loss ratio estimates are uncertain (e.g., new lines of business)
- Contracts which might be exposed to shocks which might affect expected future claims
- Contracts which have a longer settlement period (e.g., any change in future claims will have a greater second order discounting effect)

It is important to note that this consideration is around the expectations relating to remaining future coverage under the LFRC. For instance, the actual occurrence of catastrophes will impact the LFIC and will be treated in the same way under both the PAA and BBA. However, this experience may affect the entity’s expectations of future loss events, and may as such indirectly affect the PAA eligibility assessment.

Differences between the PAA and BBA will no longer exist once the coverage period of the group has ended as at that point the only liability remaining will be the LFIC and the PAA and BBA will apply the same measurement approach to this liability.8

Change in yield curves

Yield (discount rate) curves are an integral part of IFRS 17, due to the requirement under the Standard to adjust the estimates of future cash flows to reflect the time value of money and the financial risks related to those cash flows. The yield curves applied to the estimates of future cash flows should be consistent with observable market information and hence any changes in market yield curves would have an impact on the measurement of insurance liabilities.

When yield curves change from the yields at the initial recognition of the contract, differences can arise between the PAA and BBA.

The LFRC under the BBA is calculated based on the sum of the following components:
- CSM (calculated using the yield curves at initial recognition)
- Best estimate of cash flows for the remaining coverage (calculated using the current yield curves)
- Risk adjustment (calculated using the current yield curves)

For contracts without a loss component, the LFRC for the PAA is effectively based on the unearned premium, net of deferred insurance acquisition cash flows and premium receivables. An amount is included for accretion of interest if necessary9, which is based on the yield curves at initial recognition of the contract (or groups). As a result, the PAA is not affected by changes in the current yield curve unless the contract becomes onerous. For the BBA, the discounted future cash flows are affected by changes in the yield curve since the discount rates applied need to be updated at each reporting period, but the CSM is not. Therefore, if yield curves change from the initial recognition of the contract, this will result in a difference in the LFRC between the PAA and BBA.

Example 2 shows a 2-year contract which is expected to be profitable at inception. There is a change in yield curves at the end of year 1 resulting in a change to the discount rate used under the BBA. It shows how the LFRC changes under both the PAA and BBA due to a change in yield curves, with all other factors remaining equal.

8 Unless the entity chooses not to discount future cash flows for the time value of money for a LFIC under the PAA with an expected claims settlement period of less than a year.

9 IFRS 17.56 specifies that entities should adjust the carrying amount of the LFRC to reflect the time value of money and the effect of financial risks for groups of contracts that contain a significant financing component, unless the entity at initial recognition expects that the time between providing each part of the services and the related premium due date is no more than one year.
1. At inception the PAA and BBA give the same LFRC (this will always be the case).

2. If the yield curve is exactly as expected at the end of the first reporting period then the PAA and BBA will produce the same LFRC (the “Base Case”).

3. Where the yield curve decreases then the LFRC under the BBA increases as the discounted future cash flows increase (the CSM is unchanged as this is based on the yields at initial recognition) whereas the LFRC under the PAA is unchanged.

4. Where the yield curve increases then the LFRC under the BBA decreases as the discounted future cash flows decrease (the CSM is unchanged as this is based on the yields at initial recognition) whereas the LFRC under the PAA is unchanged.

5. Where the yield curve change is so significant that the discounted future cash flows are larger than the LFRC under the PAA, then a loss component is added under the PAA if facts and circumstances indicated that the group of insurance contracts had become onerous and an onerous contract test was therefore performed. Under the BBA, the discounted future cash flows are updated but the CSM is unchanged as the effect of changes in discount rates is reported in the income statement.

The impact of this difference and its significance will depend on the following sensitivities:

- The length of the coverage period.
- How large the discounting impact was to start with (current low interest environments in many economies mean that the impact is often small for these portfolios).
- How large a change might be reasonably expected in the currencies of the liabilities during the coverage period.
- Claims settlement pattern of the liabilities, as longer tailed business are more likely to be affected by discounting than shorter tailed business.

Under the PAA, an entity can choose not to adjust the LFRC to reflect the time value of money if at initial recognition, the entity expects that the time between providing each part of the coverage and the related premium due date is no more than a year. If the entity chooses not to adjust the LFRC to reflect the time value of money under the PAA, then on one hand, there will be the difference of time value of money (included in the fulfillment cash flow calculations under the BBA, but not taken into account for the PAA). On the other hand, the above effect would be limited by the fact that the choice not to reflect time value of money can only be applied if the difference between the premium due date and providing each part of the coverage is one year or less (thereby limiting the impact).

---

Other factors, e.g., treatment of interest accretion, could result in a difference in LFRC between the PAA and BBA. For illustrative purposes in this example, these differences have been ignored.
**Uneven earnings pattern**

Another source of difference between the PAA and BBA arises from the difference in revenue recognition over time. In particular, the CSM under the BBA is allocated based on coverage units reflecting the expected quantity of benefits and duration of contracts in the group\(^{11}\) while revenue under the PAA is based on the passage of time or, if significantly different from passage of time, the expected pattern of release of risk\(^{12}\) (determined through the expected timing of incurred insurance service expenses).

In particular for contracts where the timing of when claims occur is not evenly spread over the passage of time due to the seasonality of claims, there could be differences in the PAA and BBA estimates of the LFRC as the release of risk may be significantly different from the passage of time. For example, property insurance contracts exposed to catastrophes tend to have uneven earnings patterns.

Example 3 shows a 2-year contract where different service (or “earning”) patterns have been used to release revenue. It shows how the LFRC can differ under the PAA and BBA.

---

### Example 3: BBA and PAA LFRC arising from different earnings patterns

**LFRC across different earnings profiles**

<table>
<thead>
<tr>
<th></th>
<th>PAA Inception of the group</th>
<th>BBA Base case</th>
<th>PAA PAA has a faster earnings pattern</th>
<th>BBA PAA has a slower earnings pattern</th>
</tr>
</thead>
</table>

At the end of the first reporting period under various circumstances

- **FCF (inc. risk adjustment)**
- **CSM**
- **LFRC (excl. loss component)**

We note the following from this example:

1. At inception the PAA and BBA give the same LFRC (this will always be the case).
2. When the earnings patterns are in line for both BBA and PAA, then the PAA and BBA will give the same\(^{10}\) LFRC (the “Base Case”).
3. Where the earnings pattern is assumed to be more accelerated under the PAA than the allocation of coverage units (e.g., through sum insured) for the BBA, then the PAA will produce a lower LFRC, and vice versa.

The impact of this difference and its significance will depend on how the coverage units are determined for the BBA and what the expected claims pattern is for the PAA release of revenue. For many contracts these will be very similar, but some contracts will exhibit differences. Note that for any contract where there is seasonality (e.g., due to a catastrophe “season”) but the contract is one year or less in coverage period, then the PAA can still be used even if there might be differences between the PAA and BBA.

In this example the risk adjustment has been chosen to be a simple percentage of the claims. The risk adjustment can also contribute to uneven earnings patterns if not released in line with claims.

---

10 Other factors, e.g., treatment of interest accretion, could result in a difference in LFRC between the PAA and BBA. For illustrative purposes in this example, these differences have been ignored.

11 IFRS 17.B119

12 IFRS 17.B126
Basis for the PAA eligibility assessment
For groups that contain contracts with a coverage period of more than one year, the entity may use the PAA if it reasonably expects that the PAA measurement of the LFRC for the group would not differ materially from the one that would be produced applying the requirements of the BBA\textsuperscript{13}.

This requirement means that the PAA eligibility has to be assessed at the level of a group. Therefore, the materiality thresholds for assessing the outcome should be determined and evaluated at the level of the group. IFRS 17 states that the criterion of paragraph 53(a) is not met if, at the inception of the group of contracts, an entity expects significant variability in the FCF that would affect the measurement of the LFRC during the period before a claim is incurred. Variability in the FCF increases with, for example\textsuperscript{14}:

- The extent of future cash flows related to any derivatives embedded in the contracts.
- The length of the coverage period of the group of contracts.

As IFRS 17 does not contain any further specific guidance on how to determine whether outcomes are materially different, judgement will need to be applied in setting the thresholds and determining how these thresholds are applied.

This requirement also introduces a need for determining future scenarios that one would reasonably expect. As IFRS 17 does not contain any specific guidance on what ‘reasonably expects’ entails, judgement will need to be applied in identifying the range of relevant scenarios within the context of the specific features and circumstances of the group (e.g., duration of the contracts, expected profitability, volatility of profitability, earnings pattern, payment pattern, currency etc.). The future scenarios should reflect the variability in the FCF the entity expects that would affect the measurement of the LFRC during the period before a claim is incurred.

Having determined how to assess whether an outcome is materially different and having identified the range of scenarios for these considerations, the entity then assesses the PAA eligibility for a specific group following this basis. The entity may also wish to consider whether to perform this testing on a sample of groups. However, care needs to be taken as the sample selected needs to be representative of the products in the portfolio covered by the assessment.

\textsuperscript{13} IFRS 17.53(a)
\textsuperscript{14} IFRS 17.54
Applying IFRS 17 PAA eligibility criteria
Once the grouping of contracts has been determined, the entity can ascertain which groups are eligible for the PAA.

For each group, the following test is performed to determine if it is eligible for treatment under the PAA in line with Diagram 1.

Diagram 1: Eligibility test for ‘not materially differ’
Do the future LFRCs differ materially in reasonably possible future scenarios?

For the groups which have contracts with coverage periods of more than one year, it is necessary to determine for each future reporting date whether the difference in LFRC under reasonably possible future scenarios is material to the group. This is determined by calculating the difference in LFRC between the PAA and BBA in a base case and a number of shocked scenarios over the duration of the coverage period. Examples of shocks to be considered could be:

- Increases/reductions in expected loss ratios
- Increases/reductions in yield curve
- Calculating the difference when the earnings pattern under the PAA is estimated to be different from the BBA.

In applying these shocked scenarios, a decision needs to be made on when to apply the shocks. There are different ways to look at shocked scenarios, for example, one such scenario at each future reporting period during the remaining coverage of the contracts or a more severe shocked scenario at one of the future reporting dates.

Various metrics could be adopted to quantify how different the outcomes are between the two approaches. One example is to compare the difference in LFRC between the PAA and BBA at each reporting date relative to the total expected premium over the coverage period. Another example may be to compare the relative difference between the PAA and BBA to the LFRC at the relevant reporting dates within the coverage period (e.g., the PAA outcome as a percentage of the BBA outcome). With this approach, an entity should consider the potential ‘gearing effect’ later in the life of the contract when the LFRC becomes small. Whichever metric is selected, the entity should assess and document the appropriateness in the context of specific groups being tested.

The entity would then have to evaluate the results of the metric in terms of PAA eligibility outcome. An approach that could be adopted is that if the largest difference over all the scenarios tested is greater than a certain (percentage) threshold of the selected metric, then the group is deemed to fail the test and is not eligible for treatment under the PAA under IFRS 17. If all the differences remain within the threshold, then the group passes the test and qualifies for treatment under the PAA. This materiality threshold should be set by management (and also discussed with the entity’s auditors).

Once this test has been passed or failed, the result will hold for all future reporting periods as the test is performed on initial recognition only. Therefore, there is no need to re-test any of the groups subsequently.

A possible approach to determining whether there are material differences under reasonably possible shocks is summarised in Diagram 2.
Diagram 2: Determining ‘not differ materially’ under reasonably possible scenarios

Model the group under both the PAA and BBA

Determine a range of scenarios that could reasonably occur

Compare the largest difference in LFRC between the PAA and BBA over all the scenarios tested with a certain percentage of the selected metric (i.e., determined threshold).

Is the difference greater than determined threshold?

Two approaches are not materially different (group can be modelled under the PAA)

No

Two approaches are materially different (group does not qualify for the PAA)

Yes
4 Operational impact of PAA eligibility testing
To assess PAA eligibility, a bespoke model will need to be developed to assess the difference between the two approaches. This could be implemented using measurement models with the following capabilities:

1. Process to input the data from the main policy data systems. These data items will include, for example, premiums, acquisition costs, claims and expense cash flows, earnings profiles, coverage units and interest rates.

2. Model the LFRC for the base case and the shocked scenarios under the PAA and BBA.

3. Allow the user to set the parameters for the shocked scenarios and the materiality thresholds.

4. Apply the shocks at any future period specified by the user.

This model would require an initial cost to set up the process and integrate it with the data systems. There would then be an ongoing running cost for the process to be carried out at each reporting period. The cost of setting up the model and the process would be expected to be minimal when compared with implementing the BBA at a full scale. The continued running cost should be small.

If based on the PAA eligibility assessment, some groups are not eligible for the PAA, then the BBA will need to be adopted for these groups. This would have a significant operational impact since when compared to the PAA, the BBA is more costly to implement and less aligned to the current accounting and reporting practices applied to non-life insurance contracts under IFRS 4.

The following styles of abbreviation are used in these International GAAP® Illustrative disclosures:

- **12mECL**: 12 month expected credit loss
- **AFS**: Available for sale
- **Commentary**: The commentary explains how the requirements of IFRS have been implemented in arriving at the illustrative disclosure
- **CSM**: Contractual service margin
- **EAD**: Exposure at default
- **ECL**: Expected credit loss
- **EIR**: Effective interest rate
- **FVOCI**: Fair value through other comprehensive income
- **FVPL**: Fair value through profit or loss
- **GAAP**: Generally Accepted Accounting Principles/Practice
- **GM**: General model
- **Good Insurance**: Good Insurance (International) Limited and subsidiaries for the year ended 31 December 2017
- **HTM**: Held to maturity
- **IAS 1.41**: International Accounting Standard No. 1, paragraph 41
- **IAS 1.BC13**: International Accounting Standard No. 1, Basis for Conclusions, paragraph 13
- **IASB**: International Accounting Standards Board
- **IGAAP**: EY’s International GAAP®
- **IFIE**: Insurance finance income or expenses
- **IFRS 9.5.4.1**: International Financial Reporting Standard No. 9, chapter 5.4, paragraph 1
- **IFRS 17 Appendix A**: International Financial Reporting Standard No. 17, Appendix A
- **IFRS 17.44**: International Financial Reporting Standard No. 17, paragraph 44
- **IFRS 17.B5**: International Financial Reporting Standard No. 17, Appendix B (application guidance), paragraph 5
- **L&R**: Loans and receivables
- **LFRC**: Liability for remaining coverage
- **LFIC**: Liability for incurred claims
- **LGD**: Loss given default
- **LTECL**: Lifetime expected credit loss
- **Note X**: Reference to a section of Notes that are not included in this publication, but would otherwise be required in a complete set of financial statements prepared in accordance with IFRS
- **OCI**: Other comprehensive income
- **PAA**: Premium allocation approach
- **PD**: Probability of default
- **SPPI**: Solely payments of principal and interest
- **VFA**: Variable fee approach
Introduction

The purpose of this publication is to provide illustrative disclosures to meet the requirements of IFRS 17 Insurance Contracts and IFRS 9 Financial Instruments related to groups of insurance contracts accounted for under the premium allocation approach (PAA) described in IFRS 17. The disclosures are presented as a series of extracts from a set of full financial statements for Good General Insurance (International) Limited (Good General, or the Company) for the year ended 31 December 2023. Good General is a limited liability insurance subsidiary of Good Insurance (International) Limited (Good Insurance). Good General is a fictitious entity, incorporated in the fictitious country of Euroland. The functional currency of the Company is the euro.

This publication is not a full set of illustrative financial statements in accordance with International Financial Reporting Standards (IFRS). It focuses on the new presentation and disclosure requirements arising from IFRS 17 and IFRS 9 that impact on a non-life insurance entity applying the premium allocation approach (the PAA), and it does not include all IFRS 7 disclosures not altered by IFRS 9. Furthermore, it does not consider any disclosures that may be required by other standards such as IFRS 15 Revenue from Contracts with Customers or IFRS 16 Leases. The Company adopted both IFRS 17 and IFRS 9 for the first time in the annual reporting period commencing 1 January 2023.

Good General disaggregates information presented about insurance contracts in the notes to the financial statements by major product line. Good General has four major product lines that it manages and operates independently. As it does not have debt or equity instruments that are traded in a public market and is not in the process of issuing instruments in a public market, Good General is not required to make disclosures under IFRS 8 Operating Segments. The four product lines are:

- Personal accident insurance, issuing contracts that provide compensation following an accident
- Marine insurance, issuing contracts to compensate for loss or damage to ships and cargo
- Property insurance, issuing contracts to compensate for loss or damage to structures and contents, arising from fire, theft, flood and weather damage
- Liability reinsurance assumed, issuing contracts to provide insurers with payments in the event of claims made by their policyholders for losses arising from injuries and damage to people and/or property. Reinsurance is provided on a quota share basis and includes both treaty and facultative arrangements.

The illustrative presentation and disclosures in this publication are relevant for insurance and reinsurance products issued, and reinsurance held, accounted for using the PAA in IFRS 17. Other publications illustrate disclosures for products accounted for using the default measurement model (the general model) in Good Life Insurance (International) Limited and variable fee approach (VFA) in IFRS 17.

We draw attention to the disclosures in Note 11 on insurance and reinsurance contracts that reflect the roll-forward of the net asset or liability for insurance and reinsurance contracts. These disclosures require significantly more information than is currently presented in IFRS financial statements, and it is expected that these will be one of the areas requiring most effort from preparers as part of their implementation of IFRS 17.

IFRS references are shown on the margin of each page in the document indicating the specific IFRS paragraph that outlines the accounting treatment or disclosure for the particular line item or block of narrative.

We use ‘Note X’ when referring to a section of the Notes that is not included in this publication, but would otherwise be required in a complete set of financial statements prepared in accordance with IFRS.

Some disclosures are made in these financial statements merely for illustrative purposes, even though they may relate to items or transactions that are not material for the Company.

Commentaries are provided to explain the basis for the disclosure, or to address alternative disclosures not included in the illustrative financial statements. A more comprehensive list of disclosure requirements can be found in EY’s Online International GAAP® Disclosure Checklist, and further commentary on IFRS 17 is available in EY’s Applying IFRS 17 - A closer look at the new Insurance Contracts standard. For questions that may arise as to the IFRS requirements, it is essential to refer to the relevant source material and, where necessary, to seek appropriate professional advice.

The standards applied in these illustrative disclosures are those that are relevant for this publication, were in issue as at 30 June 2020, including final amendments to IFRS 17 issued 25 June 2020, and effective for annual periods beginning on or after 1 January 2023.
The preparation approach

In order to prepare the illustrative disclosures, we have used an internally developed model containing hypothetical transactions, cash flows, assets and liabilities and have used data modelling to produce the numbers reflected.

All the figures are for illustrative purposes to demonstrate disclosure requirements of IFRS 17 and IFRS 9, and may not be realistic, or reflect actual market conditions or features of real insurance products. Further details of the products and disclosure assumptions are set out below.

The disclosures reflect modelling of several groups of contracts included in the personal accident, marine, property and liability reinsurance major product lines.

The requirements of IFRS 17 are applied to groups of insurance contracts as described in paragraphs 14-24 of IFRS 17. These groups of insurance contracts are the unit of account for IFRS 17 measurement purposes and reflect portfolio, period of issue and profitability level. Some groups are assumed to be issued in a foreign currency. Groups of contracts with different levels of profitability (both onerous and non-onerous at initial recognition) are included. The model contains reinsurance contracts held, which cede some of the risks relating to the marine insurance product groups based on a simple quota share arrangement. Where onerous contracts issued by the Company have been reinsured, a loss recovery component has been recognised. The liability reinsurance product line includes profit commission arrangements (accounted for as a non-distinct investment component in this illustrative publication). ‘Assets for insurance acquisition cash flows’ have been recognised in the statement of financial position representing acquisition cash flows that are expected to be recovered from premiums received on renewal of existing contracts (Refer to Note 11).

Other modelling and disclosure assumptions to note include:

- Premiums received from insurance and reinsurance contracts issued, less payments of reinsurance premiums for reinsurance contracts held, are mostly invested in financial assets taking the form of debt instruments
- Some financial assets are measured at fair value through profit or loss, some at fair value through other comprehensive income, while others are measured at amortised cost
- The disclosures reflect the choice (under IFRS 17.88) to disaggregate insurance finance income and expense, in respect of contracts issued in the personal accident insurance product line, between profit or loss and other comprehensive income. With the amount recognised in profit or loss determined by a systematic allocation of the expected total insurance finance income or expenses over the duration of the group of contracts. Other product lines have not made the election to disaggregate.

Key new disclosures since February 2019 publication:

This publication has been updated for the amendments to IFRS 17 issued 25 June 2020.

The most significant changes made in the light of these amendments include:

- Accounting for assets for insurance acquisition cash flows - refer to:
  - Accounting policies - Note 2.2.5.5
  - Significant estimates and judgements - Note 5.1.1
  - Detailed disclosures required by IFRS 17 included in the following notes (shaded for reference):
    - Insurance service expense - Note 6
    - Personal accident insurance - Note 11.1.1
    - Marine Insurance - Note 11.1.2
    - Liability reinsurance issued - Note 11.1.4

- Accounting for a loss-recovery component on initial recognition of an onerous group of underlying insurance contracts - refer to:

The accounting policies and Notes on pages 11 to 80 form part of, and should be read in conjunction with, these financial statements.
Commentary

Paragraph 10 of IAS 1 Presentation of Financial Statements suggests titles for the primary financial statements, such as 'Statement of profit or loss and other comprehensive income' or 'Statement of financial position'. Entities are, however, permitted to use other titles, such as 'income statement' or 'balance sheet'. The Company applies the titles suggested in IAS 1.

The Company has elected as an accounting policy choice to present a single statement of profit or loss and other comprehensive income rather than two statements - a statement of profit or loss and a statement of comprehensive income. IFRS 17.80 requires entities to disaggregate the amounts recognised in the statement of profit or loss and other comprehensive income (OCI) into: an insurance service result, comprising insurance revenue and insurance service expenses, and insurance finance income or expenses.

Alternatively, the Company could consider a different layout of the statement of profit or loss and other comprehensive income considering the requirement in IAS 1.82(a) to present the total revenue on the face of the statement of profit or loss depending on its activities and other sources of revenue.

IFRS 17.81 gives entities the option to disaggregate the change in risk adjustment for non-financial risk between the insurance service result and insurance finance income or expenses. If entities do not make such a disaggregation, they must include the entire change in the risk adjustment for non-financial risk as part of the insurance service result. The Company elected not to disaggregate the change in risk adjustment for non-financial risk and includes the entire change as part of the insurance service result.

IFRS 17.86 allows entities to select one of the following presentation options: (i) to present the income or expenses from a group of reinsurance contracts held, other than insurance finance income or expenses, as a single amount; or (ii) to present separately the amounts to be recovered from the reinsurer and an allocation of the premiums paid that together give a net amount equal to that single amount. The Company has elected to present the amounts recoverable from the reinsurer and an allocation of the premiums paid separately. Amounts relating to the recovery of losses relating to reinsurance of onerous direct contracts are included as amounts recoverable from the reinsurer.

IAS 1.97 requires entities to disclose the nature and amounts of expenses when significant, therefore a further breakdown of insurance service expenses and other income and expense may be required in the notes to financial statements. The requirement has not been affected by IFRS 17 or IFRS 9.

IAS 1.82(a), as updated with effect from the date an entity applies IFRS 9, requires the separate disclosure of interest revenue calculated using the effective interest method.

IFRS 17.88 provides an accounting policy choice relating to insurance finance income and expenses (IFIE). Total IFIE may either be presented in profit or loss as a whole, or it can be disaggregated between profit or loss and other comprehensive income (OCI). The amount presented in profit or loss is determined by a systematic allocation of the expected total IFIE over the duration of the group of insurance contracts.

For groups of contracts to which an entity chooses to disaggregate IFIE between profit or loss and OCI, IFRS 17 specifies the mechanism for determining amounts recognised in profit or loss in a period. The amount included in OCI in a period is the difference between total IFIE and the amount recognised in profit or loss. The standard allows this choice to be made at a portfolio level.

IFIE comprises the change in the carrying amount of the group of insurance contracts arising from:
(a) the effect of the time value of money and changes in the time value of money; and
(b) the effect of financial risk and changes in financial risk.

Insurers are likely to identify the assets they hold that relate to different portfolios of insurance contracts. If the related assets are predominantly measured at amortised cost or fair value through other comprehensive income (FVOCI), then they might choose to disaggregate IFIE for the related portfolio of insurance contracts issued or held between profit or loss and OCI. If the related assets are predominantly measured at fair value through profit or loss (FVPL), entities might not choose to disaggregate IFIE between profit or loss and OCI.

For groups of personal accident insurance contracts, the Company systematically allocates expected total IFIE over the duration of the group of contracts to profit or loss using discount rates determined on initial recognition of the liability for incurred claims for the group of contracts (see Note 5.1.3 for current discount rates). In the event of transfer of a group of insurance contracts or the derecognition of an insurance contract, the IFIE is transferred to profit or loss. For other groups of insurance contracts, the Company does not disaggregate IFIE between profit or loss and OCI.

Commentary - Statement of financial position

Paragraph 60 of IAS 1 requires entities to present assets and liabilities either in order of their liquidity or by a separate classification on the face of the statement of financial position for current and non-current assets, and current and non-current liabilities, whichever provides information that is most reliable and relevant. The Company has presented its assets and liabilities in order of liquidity. A distinction based on expectations regarding recovery or settlement within 12 months after the reporting date and more than 12 months after the reporting date is presented in the Note 3.2.1.

Under IAS 1.10(f), an entity must present an opening statement of financial position (‘third balance sheet’) when it changes its accounting policies, makes retrospective restatements or makes reclassifications, and that change has a material effect on the statement of financial position. As per paragraph 79 of IFRS 17, any assets for insurance acquisition cash flows recognised are included in the carrying amount of the related portfolios of insurance contracts issued.

To apply IFRS 17 retrospectively, at the transition date entities must: identify, recognise and measure each group of insurance contracts as if IFRS 17 had always applied; derecognise any existing balances that would not exist had IFRS 17 always applied; and recognise any resulting net difference in equity.

### Commentary - Statement of changes in equity

The Company included lines for the impact of initial recognition of IFRS 17 and IFRS 9 that show the impact of the restatement to opening balances as at the transition date.

The statement of changes in equity includes an insurance/reinsurance finance reserve for the impact of changes in market discount rates on the insurance contract liabilities in the personal accident insurance product line. The Company has presented its statement of changes in equity net of tax, but presentation gross of tax and a corresponding line for related taxation is also acceptable.
Statement of cash flows

**Commentary**

For the purposes of this publication, we have not provided an illustrative cash flow statement. The layout of the Statement of cash flows has not been specifically changed by IFRS 17 or IFRS 9. Refer to the Statement of Cash flows in EY’s *Good Insurance (2017) publication*. 
Scope of the publication

Please refer to Appendix 1 - Scope of the Publication for a summary of the disclosures required by IFRS 17 and IFRS 7 covered in this publication.

Notes to the Financial Statements

Commentary
The following accounting policies and notes do not represent a complete set of accounting policies for a non-life insurer, but are a series of extracts relevant for this publication. We use ‘Note X’ when referring to notes that are not included in this publication, but would otherwise be required in a complete set of financial statements prepared in accordance with IFRS.

Good General presents disaggregated information about insurance contracts and reinsurance contracts by major product line in line with paragraph 95 and 96 of IFRS 17. The Company has four major product lines that it manages and operates independently: personal accident insurance, marine insurance, property insurance and liability reinsurance assumed. As each product line is managed and operates separately, the Company decided that this level of disaggregation would provide a basis for the users of the financial statements to assess the effect that contracts within the scope of IFRS 17 have on the financial position, financial performance and cash flows. In the Company’s judgement, this level of disaggregation was necessary to ensure that useful information was not obscured either by the inclusion of a large amount of insignificant detail or by the aggregation of items that have different characteristics. Entities will make their own judgements about the appropriate level of disaggregation for their businesses and are not required by IFRS 17 to disaggregate information in the same way or at the same level of detail as the Company. Once the decision for appropriate level of disaggregation is made, then the IFRS 17 disclosures need to be provided separately for each unit of aggregation.

1. Changes in accounting policies and disclosures
1.1. New and amended standards and interpretations
In these financial statements, the Company has applied IFRS 17 and IFRS 9 for the first time. The Company has not early adopted any other standard, interpretation or amendment that has been issued but is not yet effective.

1.1.1. IFRS 17 Insurance Contracts
IFRS 17 replaces IFRS 4 Insurance Contracts for annual periods on or after 1 January 2023.

The Company has restated comparative information for 2022 applying the transitional provisions in Appendix C to IFRS 17. The nature of the changes in accounting policies can be summarised, as follows:

1.1.1.1. Changes to classification and measurement
The adoption of IFRS 17 did not change the classification of the Company’s insurance contracts.

The Company was previously permitted under IFRS 4 to continue accounting using its previous (Euroland GAAP) accounting policies. However, IFRS 17 establishes specific principles for the recognition and measurement of insurance contracts issued and reinsurance contracts held by the Company.

Under IFRS 17, the Company’s insurance contracts issued and reinsurance contracts held are all eligible to be measured by the PAA. The PAA simplifies the measurement of insurance contracts in comparison with the general model in IFRS 17.

The measurement principles of the PAA differ from the ‘earned premium approach’ used by the Company under IFRS 4 in the following key areas:

- The liability for remaining coverage reflects premiums received less deferred insurance acquisition cash flows and less amounts recognised in revenue for insurance services provided
- Measurement of the liability for remaining coverage includes an adjustment for the time value of money and the effect of financial risk where the premium due date and the related period of services are more than 12 months apart
- Measurement of the liability for remaining coverage involves an explicit evaluation of risk adjustment for non-financial risk when a group of contracts is onerous in order to calculate a loss component (previously these may have formed part of the unexpired risk reserve provision)
- Measurement of the liability for incurred claims (previously claims outstanding and incurred-but-not-reported (IBNR) claims) is determined on a discounted probability-weighted expected value basis, and includes an explicit risk adjustment for non-financial risk. The liability includes the Company’s obligation to pay other incurred insurance expenses.
- Measurement of the asset for remaining coverage (reflecting reinsurance premiums paid for reinsurance held) is adjusted to include a loss-recovery component to reflect the expected recovery of onerous contract losses where such contracts reinsure onerous direct contracts.

11 Good General Insurance (International) Limited - Premium allocation approach
1.1. New and amended standards and interpretations (continued)

The Company expenses its insurance acquisition cash flows for its property insurance product line immediately upon payment and capitalises insurance acquisition cash flows for all other product lines.

For product lines where insurance acquisition cash flows are not immediately expensed, the Company allocates the acquisition cash flows to groups of insurance contracts issued or expected to be issued using a systematic and rational basis. Insurance acquisition cash flows include those that are directly attributable to a group and to future groups that are expected to arise from renewals of contracts in that group. Where such insurance acquisition cash flows are paid (or where a liability has been recognised applying another IFRS standard) before the related group of insurance contracts is recognised, an asset for insurance acquisition cash flows is recognised. When insurance contracts are recognised, the related portion of the asset for insurance acquisition cash flows is derecognised and subsumed into the measurement at initial recognition of the insurance liability for remaining coverage of the related group.

**Commentary**

In accordance with paragraph 59(a) of IFRS 17, entities may choose to recognise any insurance acquisition cash flows as an expense when it incurs those costs, provided the coverage period of each contract in the group is no more than one year. Where this option is not chosen, acquisition cash flows are required by paragraphs 28A and B35A of IFRS 17 to be allocated to groups of insurance contracts.

IFRS 4 does not prescribe the accounting treatment for insurance acquisition cash flows, therefore, if the accounting treatment chosen under IFRS 17 differs from their previous treatment, entities should disclose this change as required by paragraph 28(c) of IAS 8.

The Company’s classification and measurement of insurance and reinsurance contracts is explained in Note 2.1.

1.1.1.2. Changes to presentation and disclosure

For presentation in the statement of financial position, the Company aggregates insurance and reinsurance contracts issued and reinsurance contracts held, respectively and presents separately:

- Portfolios of insurance and reinsurance contracts issued that are assets
- Portfolios of insurance and reinsurance contracts issued that are liabilities
- Portfolios of reinsurance contracts held that are assets
- Portfolios of reinsurance contracts held that are liabilities

The portfolios referred to above are those established at initial recognition in accordance with the IFRS 17 requirements.

Portfolios of insurance contracts issued include any assets for insurance acquisition cash flows.

The line item descriptions in the statement of profit or loss and other comprehensive income have been changed significantly compared with last year. Previously, the Company reported the following line items:

- Gross written premiums
- Net written premiums
- Changes in premium reserves
- Gross insurance claims
- Net insurance claims

Instead, IFRS 17 requires separate presentation of:

- Insurance revenue
- Insurance service expenses
- Insurance finance income or expenses
- Income or expenses from reinsurance contracts held

The Company provides disaggregated qualitative and quantitative information about:

- Amounts recognised in its financial statements from insurance contracts
- Significant judgements, and changes in those judgements, when applying the standard
Notes to the Financial Statements

1.1. New and amended standards and interpretations (continued)

1.1.1.3. Transition

On transition date, 1 January 2022, the Company:

- Has identified, recognised and measured each group of insurance contracts as if IFRS 17 had always applied
- Has identified, recognised and measured assets for insurance acquisition cash flows as if IFRS 17 has always applied. However no recoverability assessment was performed before the transition date. At transition date, a recoverability assessment was performed and no impairment loss was identified
- Derecognised any existing balances that would not exist had IFRS 17 always applied
- Recognised any resulting net difference in equity

Commentary

For the purposes of the transition requirements in IFRS 17, the date of initial application is the beginning of the annual reporting period in which an entity first applies IFRS 17 (i.e., 1 January 2023 for an entity first applying the standard with an annual reporting period ending 31 December 2023). IFRS 17 also refers to the transition date as the beginning of the annual reporting period immediately preceding the date of initial application (i.e., 1 January 2022 for an entity first applying the standard with an annual reporting period ending 31 December 2023).

IFRS 17.C3(a) states that an entity is not required to present the quantitative information required by paragraph 28(f) of IAS 8 Accounting Policies, Changes in Accounting Estimates and Errors. IAS 8.28(f) requires, for the current period and each prior period presented, disclosure of the amount of the accounting policy change adjustment for each financial statement line item affected, and for basic and diluted earnings per share. No detailed reconciliation is required upon transition to IFRS 17.

For the purposes of these illustrative disclosures it has been assumed that Good General was able to apply IFRS 17 retrospectively to identify, recognise and measure and calculate assets for insurance acquisition cash flows at the transition date. If this is impracticable for an entity, it could measure the assets for insurance acquisition cash flows using either:

(a) Modified retrospective approach

If the modified retrospective approach is applied for certain groups of contracts, IFRS 17 requires an entity to use the same systematic and rational method expected to be used post transition to allocate any insurance acquisition cash flows paid (or for which a liability has been recognised applying another IFRS standard) before the transition date to groups of insurance contracts recognised at transition date and after the transition date.

To the extent that an entity does not have reasonable and supportable information to apply a systematic and rational method of allocation, any asset for insurance acquisition cash flows for groups of insurance contracts must be set to nil.

(b) Fair value approach

In applying the fair value approach, the amount of the asset for insurance acquisition cash flows must be determined as the amount of insurance acquisition cash flows that an entity would incur at the transition date to obtain rights to:

(a) Recover insurance acquisition cash flows from premiums of insurance contracts issued before the transition date but not yet recognised at the transition date;

(b) Future insurance contracts that are renewals of insurance contracts recognised at the transition date and insurance contracts described in (a); and

(c) Future insurance contracts, other than those in (b), after the transition date without paying again insurance acquisition cash flows the entity has already paid that are directly attributable to the related portfolio of insurance contracts.

At the transition date, the standard requires entities to exclude from the measurement of any group of insurance contracts the amount of any asset for insurance acquisition cash flows.
1.1. New and amended standards and interpretations (continued)

1.1.2. IFRS 9 Financial Instruments

IFRS 9 replaced IAS 39 Financial Instruments: Recognition and Measurement for annual periods beginning on or after 1 January 2018. However, the Company elected, under the amendments to IFRS 4, to apply the temporary exemption from IFRS 9, thereby deferring the initial application date of IFRS 9 to align with the initial application of IFRS 17.

The Company has applied IFRS 9 retrospectively and restated comparative information for 2022 for financial instruments in the scope of IFRS 9. Differences arising from the adoption of IFRS 9 were recognised in retained earnings as of 1 January 2022 and are disclosed in Note 1.1.3.

Commentary

Comparative information for instruments in the scope of IFRS 9 may only be restated if this is possible without the use of hindsight. For the purposes of these illustrative disclosures it has been assumed that Good General Insurance was able to restate comparatives without the use of hindsight.

As per IFRS 9.7.2.1, IFRS 9 must not be applied to items that have already been derecognised at the date of initial application. As such, if an entity chooses to restate comparatives, IAS 39 must continue to be applied to any items derecognised during the comparative period. For the purposes of these illustrative disclosures, it has been assumed that Good General did not derecognise any IAS 39 assets during 2022. Accordingly, IFRS 9 is applied to all financial instruments for the comparative period.

If an entity restating comparative information has assets that were disposed of in the comparative period, the entity will apply IAS 39 recognition and measurement requirements to those assets in the comparative period. It will also need to produce the relevant IAS 39 related disclosures for these assets including:

- The IAS 39 accounting for gains/losses and income on such assets in the statement of profit or loss
- IAS 39 classifications for the restated opening statement of financial position
- Relevant IAS 39 accounting policies
- Any relevant note disclosures

For illustrative IAS 39 related disclosures please refer to EY’s Good Insurance (2017) publication.

The nature of the changes in accounting policies can be summarised, as follows:

1.1.2.1. Changes to classification and measurement

To determine their classification and measurement category, IFRS 9 requires all financial assets to be assessed based on a combination of the Company’s business model for managing the assets and the instruments’ contractual cash flow characteristics.

The IAS 39 measurement categories for financial assets (fair value through profit or loss (FVPL), available for sale (AFS), held-to-maturity (HTM) and loans and receivables (L&R) at amortised cost) have been replaced by:

- Financial assets at fair value through profit or loss, including equity instruments and derivatives
- Debt instruments at fair value through other comprehensive income, with gains or losses recycled to profit or loss on derecognition
- Equity instruments at fair value through other comprehensive income, with no recycling of gains or losses to profit or loss on derecognition (not used by the Company)
- Debt instruments at amortised cost

The Company’s classification of its financial assets is explained in Note 2.3. The quantitative impact of applying IFRS 9 as at 1 January 2022 is disclosed in Note 1.1.3.
1.1. New and amended standards and interpretations (continued)

1.1.2.2. Changes to the impairment calculation

The adoption of IFRS 9 has fundamentally changed the Company’s accounting for impairment losses for debt instruments held at FVOCI or amortised cost by replacing IAS 39’s incurred loss approach with a forward-looking expected credit loss (ECL) approach.

IFRS 9 requires the Company to record an allowance for ECLs for all debt instruments not held at FVPL.

For debt instruments, the ECL is based on the portion of lifetime ECLs (LTECL) that would result from default events on a financial instrument that are possible within 12 months after the reporting date. However, when there has been a significant increase in credit risk since origination or purchase of the assets, the allowance is based on the full LTECL.

The Company’s debt instruments at FVOCI and amortised cost comprise quoted bonds that are graded in the top investment category (Very Good and Good) by the Euroland Credit Agency and, therefore, are considered to be low credit risk investments. It is the Company’s policy to measure such instruments on a 12-month ECL (12mECL) basis. The Company does, however, consider that there has been a significant increase in credit risk for a previously assessed low credit risk investment when any contractual payments on these instruments are more than 30 days past due. Where the credit risk of any bond deteriorates, the Company will sell the bond and purchase bonds meeting the required investment grade.

The Company considers an instrument to be in default when contractual payments are 90 days past due. However, in certain cases, the Company may also consider an instrument to be in default when internal or external information indicates that the Company is unlikely to receive the outstanding contractual amounts in full. There were no such instances in 2023 or 2022.

The adoption of the ECL requirements of IFRS 9 has resulted in increases in impairment allowances in respect of the Company’s debt instruments. The increase in allowance was adjusted to retained earnings.

As it was possible to do so without the use of hindsight, the Company restated the statement of financial position as at 1 January 2022, resulting in decreases in financial assets and retained earnings amounting to €11,000, respectively. The statement of profit or loss for the year ended 31 December 2022 was also restated, resulting in increases in impairment loss on financial assets amounting to €2,000.

Details of the Company’s impairment method are disclosed in Note 2.3.6. The quantitative impact of applying IFRS 9 as at 1 January 2022 is disclosed in Note 1.1.3.

1.1.2.3. Changes in disclosure - IFRS 7

To reflect the differences between IFRS 9 and IAS 39, IFRS 7 Financial Instruments: Disclosures was also amended. The Company applied the amended disclosure requirements of IFRS 7, together with IFRS 9, for the year beginning 1 January 2023. Changes include transition disclosures as shown in Note 1.1.3. Detailed qualitative and quantitative information about the ECL calculations, such as the assumptions and inputs used, are set out in Notes 2.3.6.1 and 5.2.1.

Reconciliations from opening to closing ECL allowances are presented in Notes 3.2.4.4.1 and 3.2.4.4.2.

Commentary

IFRS 7 also requires additional and more detailed disclosures for hedge accounting even for entities opting to continue to apply the hedge accounting requirements of IAS 39.

For the purposes of these illustrative disclosures, it has been assumed that Good General does not hedge account and, as such, these disclosures have not been included.
1.1. New and amended standards and interpretations (continued)

1.1.3. Transition disclosures - IFRS 9

The following pages set out the impact of adopting IFRS 9 on the statement of financial position, including the effect of replacing IAS 39’s incurred credit loss calculations with IFRS 9’s ECLs.

A reconciliation between the carrying amounts under IAS 39 and the balances reported under IFRS 9 as of initial application date 1 January 2023 is, as follows:

1. Loans and receivables
2. Amortised cost
3. Available for sale

A As of 1 January 2023, the Company classified a portion of its previous AFS portfolio as debt instruments at amortised cost. These instruments met the solely payments of principal and interest (SPPI) criterion, were not actively traded and were held with the intention to collect cash flows and without the intention to sell. The fair value of these instruments that the Company still held at 31 December 2023 was €1,005,000. The change in fair value over 2023 that would have been recorded in OCI had these instruments continued to be revalued through OCI, is €4,000.

B As of 1 January 2023, the Company assessed the remainder of its debt instrument portfolio which had previously been classified as AFS debt instruments. The Company concluded that these instruments are managed within a business model of collecting contractual cash flows and selling the financial assets. Accordingly, the Company classified these investments as debt instruments measured at FVOCI.

C As at 1 January 2023, the Company assessed its assets previously designated at FVPL under IAS 39. Under IFRS 9, the Company classifies all its equity instruments as mandatorily measured at FVPL. In respect of debt instruments previously designated FVPL under IAS 39, upon evaluation, as the Company’s business model is to manage this portfolio of instruments on a fair value basis, these assets did not meet the criterion for recognition at amortised cost or FVOCI and as such are mandatorily measured at FVPL.

D The impact of adopting IFRS 9 on deferred tax is set out on the next page and in Note X.

Commentary

On initial application of IFRS 9, entities are required to revisit the FVPL designations previously made in accordance with IAS 39 and are also given an opportunity to make new designations in accordance with IFRS 9. More specifically, on the date of initial application:

- Any previous designation of a financial asset as measured at FVPL may be revoked in any case, but must be revoked if such designation no longer eliminates, or significantly reduces, an accounting mismatch.
- A financial asset or a financial liability may be designated as measured at FVPL, if such designation would now eliminate or significantly reduce an accounting mismatch.
- Any previous designation of a financial liability as measured at FVPL that was made on the basis that it eliminated or significantly reduced an accounting mismatch may be revoked in any case, but must be revoked if such designation no longer eliminates or significantly reduces an accounting mismatch.
- Any investment in a non-derivative equity instrument that meets the definition of equity under IAS 32 and is not held for trading, may be designated as non-recyclable FVOCI. The Company does not make use of this measurement category.

Under IAS 39, in certain circumstances, entities may choose to elect to hold equity instruments at cost. The option to hold such investments at cost is no longer available under IFRS 9. The Company did not elect to use that option in the past.

We specifically draw attention to IFRS 7.42M-N that requires the following disclosures where financial assets are reclassified to amortised cost:

- The fair value of the financial asset at the year end and the fair value gains and losses that would have been recognised in profit or loss during the period if the assets had not been reclassified.

And when entities reclassify financial assets out of FVPL into FVOCI or amortised cost:

- The effective interest rate (EIR) determined on the date of initial application and the recognised interest revenue or expense.

We have addressed these disclosures, as relevant, in the narrative part of the transition tables.

For the purposes of these disclosures, we assumed the deferred tax balances can be offset in accordance with the requirements of IAS 12 Income Taxes.

IFRS 7 includes disclosure requirements at the date of initial application of IFRS 9 (1 January 2023). As Good General has restated comparative balances effective 1 January 2022, the following additional tables have been included to provide the user with additional information about the transition to IFRS 9 and the adjustments to opening balances of retained earnings and the fair value reserve as at 1 January 2022, in conjunction with the effects of the transition to IFRS 17 on that date.

#### Commentary

The disclosures of the impact of the transition to IFRS 9 on reserves and retained earnings, deferred tax and provisions are not specified by IFRS 9 and IFRS 7. However, providing such disclosures is in line with both IAS 1.106(b) and IAS 8.28(f), which require entities to disclose the effects of retrospective application. IAS 1.17(c) and IAS 1.38 also require entities to provide additional disclosures when otherwise the information would be insufficient to enable users to understand the impact of particular transactions and to assist comparability.
2. Summary of significant accounting policies

2.1. Insurance and reinsurance contracts classification

The Company issues insurance contracts in the normal course of business, under which it accepts significant insurance risk from its policyholders. As a general guideline, the Company determines whether it has significant insurance risk, by comparing benefits payable after an insured event with benefits payable if the insured event did not occur. Insurance contracts can also transfer financial risk. The Company issues non-life insurance to individuals and businesses. Non-life insurance products offered include property, marine, and personal accident. These products offer protection of policyholder's assets and indemnification of other parties that have suffered damage as a result of a policyholder's accident.

The Company also issues reinsurance contracts in the normal course of business to compensate other entities for claims arising from one or more insurance contracts issued by those entities.

The Company does not issue any contracts with direct participating features.

Commentary

The definition of an insurance contract in IFRS 17 is ‘a contract under which one party (the insurer) accepts significant insurance risk from another party (the policyholder) by agreeing to compensate the policyholder if a specified uncertain future event (the insured event) adversely affects the policyholder’.

The definition of an insurance contract refers to ‘insurance risk’ which is defined as ‘risk, other than financial risk, transferred from the holder of a contract to the issuer’.

This definition determines which contracts are within the scope of IFRS 17 rather than other standards.

The basic definition of an insurance contract is unchanged from IFRS 4, which means that, in many cases, contracts that were insurance contracts under IFRS 4 are expected to be insurance contracts under IFRS 17. However, there have been clarifications to the related application guidance explaining the definition to require that:

- An insurer should consider the time value of money in assessing whether the additional benefits payable in any scenario are significant
- A contract does not transfer significant insurance risk if there is no scenario with commercial substance in which the insurer can suffer a loss on a present value basis
- If a reinsurance contract does not expose the insurer to the possibility of a significant loss, that contract is still deemed to transfer significant insurance risk, if it transfers to the reinsurer substantially all the insurance risk relating to the reinsured portions of the underlying insurance contracts. This guidance in IFRS 17.B19 is new compared to that contained in IFRS 4

Insurance risk is significant if, and only if, an insured event could cause the issuer to pay additional amounts that are significant in any single scenario, excluding scenarios that have no commercial substance (i.e., no discernible effect on the economics of the transaction). If an insured event could mean significant additional amounts would be payable in any scenario that has commercial substance, the condition in the previous sentence can be met even if the insured event is extremely unlikely, or even if the expected (i.e., probability-weighted) present value of the contingent cash flows is a small proportion of the expected present value of the remaining cash flows from the insurance contract.

The additional amounts described above are determined on a present value basis. If an insurance contract requires payment when an event with uncertain timing occurs and if the payment is not adjusted for the time value of money, there may be scenarios in which the present value of the amount increases, even if its nominal value is fixed.

No quantitative guidance supports the determination of ‘significant’ in IFRS 17. This was a deliberate decision because the IASB considered that if quantitative guidance was provided, it would create an arbitrary dividing line that would result in different accounting treatments for similar transactions that fall marginally on different sides of that line. This would therefore create opportunities for accounting arbitrage.

IFRS 4 contained an illustrative example which implied insured benefits must be greater than 101% of the benefits payable if the insured event did not occur for there to be insurance risk in an insurance contract. However, no equivalent example has been included in IFRS 17. It is not disputed in the Basis for Conclusions that a 10% chance of a 10% loss results in a transfer of significant insurance risk and, indeed, the words ‘extremely unlikely’ and ‘a small proportion’ suggests that the IASB envisages that significant insurance risk could exist at a different threshold than a 10% probability of a 10% loss.

This lack of a quantitative definition means that insurers must apply their own judgement as to what constitutes significant insurance risk. Although the IASB did not want to create an ‘arbitrary dividing line’, the practical impact of this lack of guidance is that insurers have to apply their own criteria to what constitutes significant insurance risk. As such, there will likely, be inconsistency in practice as to what these dividing lines are, at least at the margins.
Notes to the Financial Statements

2.1. Insurance and reinsurance contracts classification (continued)

There is no specific requirement under IFRS 17 for insurers to disclose any thresholds used in determining whether a contract contains significant insurance risk. However, IFRS 17 requires an entity to disclose the significant judgements made in applying IFRS 17, whilst IAS 1 Presentation of Financial Statements requires an entity to disclose the judgements that management has made in the process of applying the entity's accounting policies that have the most significant effect on the amounts recognised in the financial statements.

IFRS 17 requires the assessment of whether a contract transfers significant insurance risk to be made only once (unless the terms of the contract are modified). The Basis for Conclusions states that this assessment is made at inception.

As the assessment of significant insurance risk is made only once, a contract that qualifies as an insurance contract remains an insurance contract until all rights and obligations are extinguished (i.e., discharged, cancelled or expired), unless the contract is derecognised because of a modification.

2.2. Insurance and reinsurance contracts accounting treatment

2.2.1. Separating components from insurance and reinsurance contracts

The Company assesses its non-life insurance and reinsurance products to determine whether they contain distinct components which must be accounted for under another IFRS instead of under IFRS 17. After separating any distinct components, the Company applies IFRS 17 to all remaining components of the (host) insurance contract. Currently, the Company's products do not include any distinct components that require separation.

Some reinsurance contracts issued contain profit commission arrangements. Under these arrangements, there is a minimum guaranteed amount that the policyholder will always receive - either in the form of profit commission, or as claims, or another contractual payment irrespective of the insured event happening. The minimum guaranteed amounts have been assessed to be highly interrelated with the insurance component of the reinsurance contacts and are, therefore, non-distinct investment components which are not accounted for separately. However, receipts and payments of these investment components are recognised outside of profit or loss.

2.2.2. Level of aggregation

IFRS 17 requires a company to determine the level of aggregation for applying its requirements. The Company previously applied aggregation levels under Euroland GAAP, which were significantly higher than the level of aggregation required by IFRS 17. The level of aggregation for the Company is determined firstly by dividing the business written into portfolios. Portfolios comprise groups of contracts with similar risks which are managed together. Portfolios are further divided based on expected profitability at inception into three categories: onerous contracts, contracts with no significant risk of becoming onerous, and the remainder. This means that, for determining the level of aggregation, the Company identifies a contract as the smallest 'unit', i.e., the lowest common denominator. However, the Company makes an evaluation of whether a series of contracts need to be treated together as one unit based on reasonable and supportable information, or whether a single contract contains components that need to be separated and treated as if they were stand-alone contracts. As such, what is treated as a contract for accounting purposes may differ from what is considered as a contract for other purposes (i.e., legal or management). IFRS 17 also requires that no group for level of aggregation purposes may contain contracts issued more than one year apart.

The Company has elected to group together those contracts that would fall into different groups only because law or regulation specifically constrains its practical ability to set a different price or level of benefits for policyholders with different characteristics.

The Company applied a full retrospective approach for transition to IFRS 17. The portfolios are further divided by year of issue and profitability for recognition and measurement purposes. Hence, within each year of issue, portfolios of contracts are divided into three groups, as follows:

- A group of contracts that are onerous at initial recognition (if any)
- A group of contracts that, at initial recognition, have no significant possibility of becoming onerous subsequently (if any)
- A group of the remaining contracts in the portfolio (if any)
2.2. Insurance and reinsurance contracts accounting treatment (continued)

The profitability of groups of contracts is assessed by actuarial valuation models that take into consideration existing and new business. The Company assumes that no contracts in the portfolio are onerous at initial recognition unless facts and circumstances indicate otherwise. For contracts that are not onerous, the Company assesses, at initial recognition, that there is no significant possibility of becoming onerous subsequently by assessing the likelihood of changes in applicable facts and circumstances. The Company considers facts and circumstances to identify whether a group of contracts are onerous based on:

- Pricing information
- Results of similar contracts it has recognised
- Environmental factors, e.g., a change in market experience or regulations

The Company divides portfolios of reinsurance contracts held applying the same principles set out above, except that the references to onerous contracts refer to contracts on which there is a net gain on initial recognition. For some groups of reinsurance contracts held, a group can comprise a single contract.

2.2.3. Recognition

The Company recognises groups of insurance contracts it issues from the earliest of the following:

- The beginning of the coverage period of the group of contracts
- The date when the first payment from a policyholder in the group is due or when the first payment is received if there is no due date
- For a group of onerous contracts, if facts and circumstances indicate that the group is onerous

The Company recognises a group of reinsurance contracts held it has entered into from the earlier of the following:

- The beginning of the coverage period of the group of reinsurance contracts held. (However, the Company delays the recognition of a group of reinsurance contracts held that provide proportionate coverage until the date any underlying insurance contract is initially recognised, if that date is later than the beginning of the coverage period of the group of reinsurance contracts held.

And

- The date the Company recognises an onerous group of underlying insurance contracts if the Company entered into the related reinsurance contract held in the group of reinsurance contracts held at or before that date.

The Company adds new contracts to the group in the reporting period in which that contract meets one of the criteria set out above.

Commentary:

The issue date of a contract is when an entity has a contractual obligation to accept risk. The issue date is typically before the beginning of coverage and due date for the initial premium. However, IFRS 17 only requires recognition of issued insurance contracts before these dates if facts and circumstances indicate that the contracts in the group to which the PAA applies are onerous. The recognition requirements for reinsurance contracts held that provide proportionate coverage are intended to simplify recognition for proportionate reinsurance contracts held. Circumstances in which the first underlying attaching contract is issued, shortly after the reinsurance contracts are written, will result in similar timing of recognition for proportionate and ‘other-than-proportionate’ reinsurance contracts. In other cases, there may be a greater difference in the timing of recognition.
2.2. Insurance and reinsurance contracts accounting treatment (continued)

2.2.4. Contract boundary

The Company includes in the measurement of a group of insurance contracts all the future cash flows within the boundary of each contract in the group. Cash flows are within the boundary of an insurance contract if they arise from substantive rights and obligations that exist during the reporting period in which the Company can compel the policyholder to pay the premiums, or in which the Company has a substantive obligation to provide the policyholder with insurance contract services. A substantive obligation to provide insurance contract services ends when:

- The Company has the practical ability to reassess the risks of the particular policyholder and, as a result, can set a price or level of benefits that fully reflects those risks

Or

- Both of the following criteria are satisfied:
  - The Company has the practical ability to reassess the risks of the portfolio of insurance contracts that contain the contract and, as a result, can set a price or level of benefits that fully reflects the risk of that portfolio
  - The pricing of the premiums up to the date when the risks are reassessed does not take into account the risks that relate to periods after the reassessment date

A liability or asset relating to expected premiums or claims outside the boundary of the insurance contract is not recognised. Such amounts relate to future insurance contracts.
## 2.2. Insurance and reinsurance contracts accounting treatment (continued)

### 2.2.5. Measurement - Premium Allocation Approach

<table>
<thead>
<tr>
<th>IFRS 17 Options</th>
<th>Adopted approach</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Premium Allocation Approach (PAA) Eligibility</strong></td>
<td>Coverage period for property insurance and liability reinsurance assumed is one year or less and so qualifies automatically for PAA. Both marine insurance and personal accident insurance include contracts with coverage period greater than one year. However, there is no material difference in the measurement of the liability for remaining coverage between PAA and the general model, therefore, these qualify for PAA.</td>
</tr>
<tr>
<td>Insurance acquisition cash flows for insurance contracts issued</td>
<td>For one-year property business, insurance acquisition cash flows are expensed as incurred. For all other business, insurance acquisition cash flows are allocated to related groups of insurance contracts and amortised over the coverage period of the related group.</td>
</tr>
<tr>
<td>Liability for Remaining Coverage (LFRC), adjusted for financial risk and time value of money</td>
<td>For marine and personal accident insurance, an allowance is made for accretion of interest on the LFRC. For all other business, there is no allowance as the premiums are received within one year of the coverage period.</td>
</tr>
<tr>
<td>Liability for Incurred Claims, (LFIC) adjusted for time value of money</td>
<td>For some claims within the property product line, the incurred claims are expected to be paid out in less than one year. Hence, no adjustment is made for the time value of money. For all other business, the LFIC is adjusted for the time value of money.</td>
</tr>
<tr>
<td>Insurance finance income and expense</td>
<td>For the personal accident product line, the impact on LFIC of changes in discount rates will be captured within OCI, in line with the accounting for assets backing this product line. ### Commentary

The PAA provides entities with a number of accounting policy choices which have been presented above in a tabular format. As shown above, the Company has made an election for each of the five accounting policy choices available in respect of the PAA approach, as appropriate to the circumstances of the Company. In such cases, the commentary provides details of which policy has been selected, the reasons for this policy selection, and summarises the difference in the disclosure requirements. While it is not expected that entities will necessarily take a similar approach in practice, the Company has elected different accounting policy choices for its insurance product lines to demonstrate disclosures related to the options available under the PAA.

These are accounting policy choices made in accordance with IAS 8, unless indicated otherwise by IFRS 17.
2.2. Insurance and reinsurance contracts accounting treatment (continued)

2.2.5.1. Insurance contracts - initial measurement

The Company applies the premium allocation approach (PAA) to all the insurance contracts that it issues and reinsurance contracts that it holds, as:

- The coverage period of each contract in the group is one year or less, including insurance contract services arising from all premiums within the contract boundary (refer to 2.2.4)

Or

- For contracts longer than one year, the Company has modelled possible future scenarios and reasonably expects that the measurement of the liability for remaining coverage for the group containing those contracts under the PAA does not differ materially from the measurement that would be produced applying the general model. In assessing materiality, the Company has also considered qualitative factors such as the nature of the risk and types of its lines of business.

The Company does not apply the PAA if, at the inception of the group of contracts, it expects significant variability in the fulfilment cash flows that would affect the measurement of the liability for the remaining coverage during the period before a claim is incurred. Variability in the fulfilment cash flows increases with, for example:

- The extent of future cash flows related to any derivatives embedded in the contracts
- The length of the coverage period of the group of contracts

For a group of contracts that is not onerous at initial recognition, the Company measures the liability for remaining coverage as:

- The premiums, if any, received at initial recognition
- Minus any insurance acquisition cash flows at that date, with the exception of contracts which are one year or less where this is expensed,
- Plus or minus any amount arising from the derecognition at that date of the asset recognised for insurance acquisition cash flows and
- Any other asset or liability previously recognised for cash flows related to the group of contracts that the Company pays or receives before the group of insurance contracts is recognised.

For marine and personal accident insurance, the liability for remaining coverage is discounted to reflect the time value of money and the effect of financial risk. For all other business, there is no allowance for time value of money as the premiums are received within one year of the coverage period.

Where facts and circumstances indicate that contracts are onerous at initial recognition, the Company performs additional analysis to determine if a net outflow is expected from the contract. Such onerous contracts are separately grouped from other contracts and the Company recognises a loss in profit or loss for the net outflow, resulting in the carrying amount of the liability for the group being equal to the fulfilment cash flows. A loss component is established by the Company for the liability for remaining coverage for such onerous group depicting the losses recognised. For additional disclosures on the loss component, please refer to Note 2.2.6.2.

Commentary:

IFRS 17.59(b) does not require an entity to adjust future cash flows for the time value of money and the effect of financial risk if those cash flows are expected to be paid or received in one year or less from the date the claims are incurred. Nevertheless, an entity may choose to adjust future cash flows for various reasons, for example, to apply the same calculation without a necessity to analyse time period between the claims incurred and an expected date of payment.
2.2. Insurance and reinsurance contracts accounting treatment (continued)

2.2.5.2. Reinsurance contracts held - initial measurement

The Company measures its reinsurance assets for a group of reinsurance contracts that it holds on the same basis as insurance contracts that it issues. However, they are adapted to reflect the features of reinsurance contracts held that differ from insurance contracts issued, for example the generation of expenses or reduction in expenses rather than revenue.

Where the Company recognises a loss on initial recognition of an onerous group of underlying insurance contracts or when further onerous underlying insurance contracts are added to a group, the Company establishes a loss-recovery component of the asset for remaining coverage for a group of reinsurance contracts held depicting the recovery of losses.

The Company calculates the loss-recovery component by multiplying the loss recognised on the underlying insurance contracts and the percentage of claims on the underlying insurance contracts the Company expects to recover from the group of reinsurance contracts held. The Company uses a systematic and rational method to determine the portion of losses recognised on the group to insurance contracts covered by the group of reinsurance contracts held where some contracts in the underlying group are not covered by the group of reinsurance contracts held.

The loss-recovery component adjusts the carrying amount of the asset for remaining coverage.

Commentary:
A loss recovery component is recognised when an entity recognises a loss on initial recognition of an onerous group of underlying insurance contracts or on the addition of onerous underlying contracts to a group, if and only if the reinsurance contract held is entered into before or at the same time as the onerous underlying insurance contracts are recognised.

2.2.5.3. Insurance contracts - subsequent measurement

The Company measures the carrying amount of the liability for remaining coverage at the end of each reporting period as the liability for remaining coverage at the beginning of the period:

- Plus premiums received in the period
- Minus insurance acquisition cash flows, with the exception of property insurance product line for which the Company chooses to expense insurance acquisition cash flows as they occur (please see Note 2.2.5.1)
- Plus any amounts relating to the amortisation of the insurance acquisition cash flows recognised as an expense in the reporting period for the group
- Plus any adjustment to the financing component, where applicable
- Minus the amount recognised as insurance revenue for the services provided in the period
- Minus any investment component paid or transferred to the liability for incurred claims

The Company estimates the liability for incurred claims as the fulfilment cash flows related to incurred claims. The fulfilment cash flows incorporate, in an unbiased way, all reasonable and supportable information available without undue cost or effort about the amount, timing and uncertainty of those future cash flows, they reflect current estimates from the perspective of the Company, and include an explicit adjustment for non-financial risk (the risk adjustment). The Company does not adjust the future cash flows for the time value of money and the effect of financial risk for the measurement of liability for incurred claims that are expected to be paid within one year of being incurred.

Where, during the coverage period, facts and circumstances indicate that a group of insurance contracts is onerous, the Company recognises a loss in profit or loss for the net outflow, resulting in the carrying amount of the liability for the group being equal to the fulfilment cash flows. A loss component is established by the Company for the liability for remaining coverage for such onerous group depicting the losses recognised. For additional disclosures on the loss component, please refer to Note 2.2.6.2.

Insurance acquisition cash flows are allocated on a straight-line basis as a portion of premium to profit or loss (through insurance revenue).
Notes to the Financial Statements

2.2. Insurance and reinsurance contracts accounting treatment (continued)

2.2.5.4. Reinsurance contracts held - subsequent measurement

The subsequent measurement of reinsurance contracts held follows the same principles as those for insurance contracts issued and has been adapted to reflect the specific features of reinsurance held.

Where the Company has established a loss-recovery component, the Company subsequently reduces the loss-recovery component to zero in line with reductions in the onerous group of underlying insurance contracts in order to reflect that the loss-recovery component shall not exceed the portion of the carrying amount of the loss component of the onerous group of underlying insurance contracts that the entity expects to recover from the group of reinsurance contracts held.

Commentary

The standard does not include guidance on the subsequent treatment of a loss-recovery component that was recognised at initial recognition of a group of underlying insurance contracts.

Per IFRS 17 paragraph B119F, the carrying amount of the loss-recovery component shall not exceed the portion of the carrying amount of the loss component of the onerous group of underlying insurance contracts that an entity expects to recover from the group of reinsurance contracts held and thus should be nil when loss component of the onerous group of underlying insurance contracts is nil. On this basis, the loss-recovery component recognised at initial recognition should be reduced to zero in line with reductions in the onerous group of underlying insurance contracts.

2.2.5.5. Insurance acquisition cash flows

Insurance acquisition cash flows arise from the costs of selling, underwriting and starting a group of insurance contracts (issued or expected to be issued) that are directly attributable to the portfolio of insurance contracts to which the group belongs.

With the exception of the property insurance product line, for which the Company chooses to expense insurance acquisition cash flows as they occur, the Company uses a systematic and rational method to allocate:

(a) Insurance acquisition cash flows that are directly attributable to a group of insurance contracts:

(i) to that group; and

(ii) to groups that include insurance contracts that are expected to arise from the renewals of the insurance contracts in that group.

(b) Insurance acquisition cash flows directly attributable to a portfolio of insurance contracts that are not directly attributable to a group of contracts, to groups in the portfolio.

Where insurance acquisition cash flows have been paid or incurred before the related group of insurance contracts is recognised in the statement of financial position, a separate asset for insurance acquisition cash flows is recognised for each related group.

The asset for insurance acquisition cash flow is derecognised from the statement of financial position when the insurance acquisition cash flows are included in the initial measurement of the related group of insurance contracts. The time bands when the Company expects to derecognise the above asset for insurance acquisition cash flows are disclosed in Note 11.

At the end of each reporting period, the Company revises amounts of insurance acquisition cash flows allocated to groups of insurance contracts not yet recognised, to reflect changes in assumptions related to the method of allocation used.

After any re-allocation, the Company assesses the recoverability of the asset for insurance acquisition cash flows, if facts and circumstances indicate the asset may be impaired. When assessing the recoverability, the Company applies:

- An impairment test at the level of an existing or future group of insurance contracts; and
- An additional impairment test specifically covering the insurance acquisition cash flows allocated to expected future contract renewals.

If an impairment loss is recognised, the carrying amount of the asset is adjusted and an impairment loss is recognised in profit or loss.

The Company recognises in profit or loss a reversal of some or all of an impairment loss previously recognised and increases the carrying amount of the asset, to the extent that the impairment conditions no longer exist or have improved.
2.2. Insurance and reinsurance contracts accounting treatment (continued)

2.2.5.6. Insurance contracts - modification and derecognition

The Company derecognises insurance contracts when:

- The rights and obligations relating to the contract are extinguished (i.e., discharged, cancelled or expired)

Or

- The contract is modified such that the modification results in a change in the measurement model or the applicable standard for measuring a component of the contract, substantially changes the contract boundary, or requires the modified contract to be included in a different group. In such cases, the Company derecognises the initial contract and recognises the modified contract as a new contract.

When a modification is not treated as a derecognition, the Company recognises amounts paid or received for the modification with the contra contract as an adjustment to the relevant liability for remaining coverage.

2.2.6. Presentation

The Company has presented separately, in the statement of financial position, the carrying amount of portfolios of insurance contracts issued that are assets, portfolios of insurance contracts issued that are liabilities, portfolios of reinsurance contracts held that are assets and portfolios of reinsurance contracts held that are liabilities.

Any assets for insurance acquisition cash flows recognised before the corresponding insurance contracts are included in the carrying amount of the related groups of insurance contracts are allocated to the carrying amount of the portfolios of insurance contracts that they relate to.

The Company disaggregates the total amount recognised in the statement of profit or loss and other comprehensive income into an insurance service result, comprising insurance revenue and insurance service expense, and insurance finance income or expenses.

The Company does not disaggregate the change in risk adjustment for non-financial risk between a financial and non-financial portion and includes the entire change as part of the insurance service result.

The Company separately presents income or expenses from reinsurance contracts held from the expenses or income from insurance contracts issued.

2.2.6.1. Insurance revenue

The insurance revenue for the period is the amount of expected premium receipts (excluding any investment component) allocated to the period. The Company allocates the expected premium receipts to each period of insurance contract services on the basis of the passage of time. But if the expected pattern of release of risk during the coverage period differs significantly from the passage of time, then the allocation is made on the basis of the expected timing of incurred insurance service expenses.

The Company changes the basis of allocation between the two methods above as necessary, if facts and circumstances change. The change is accounted for prospectively as a change in accounting estimate.

For the periods presented, all revenue has been recognised on the basis of the passage of time.

2.2.6.2. Loss components

The Company assumes that no contracts are onerous at initial recognition unless facts and circumstances indicate otherwise. Where this is not the case, and if at any time during the coverage period, the facts and circumstances mentioned in Note 2.2.2 indicate that a group of insurance contracts is onerous, the Company establishes a loss component as the excess of the fulfilment cash flows that relate to the remaining coverage of the group over the carrying amount of the liability for remaining coverage of the group as determined in Note 2.2.5.3. Accordingly, by the end of the coverage period of the group of contracts the loss component will be zero.
Notes to the Financial Statements

2.2. Insurance and reinsurance contracts accounting treatment (continued)

Commentary
When entities apply the premium allocation approach for a group of contracts which is assessed as onerous, then a loss component should be established as per the calculation in IFRS 17.57. Given the simplified nature of the premium allocation approach, entities could also consider using practical applications that would achieve the same accounting outcome as if IFRS 17.57 were applied.

2.2.6.3. Loss-recovery components
As described in Note 2.2.5.2 above, where the Company recognises a loss on initial recognition of an onerous group of underlying insurance contracts, or when further onerous underlying insurance contracts are added to a group, the Company establishes a loss-recovery component of the asset for remaining coverage for a group of reinsurance contracts held depicting the expected recovery of the losses.

A loss-recovery component is subsequently reduced to zero in line with reductions in the onerous group of underlying insurance contracts in order to reflect that the loss-recovery component shall not exceed the portion of the carrying amount of the loss component of the onerous group of underlying insurance contracts that the entity expects to recover from the group of reinsurance contracts held.

2.2.6.4. Insurance finance income and expense
Insurance finance income or expenses comprise the change in the carrying amount of the group of insurance contracts arising from:

- The effect of the time value of money and changes in the time value of money; and
- The effect of financial risk and changes in financial risk.

The Company disaggregates insurance finance income or expenses on insurance contracts issued for its personal accident product line between profit or loss and OCI. The impact of changes in market interest rates on the value of the insurance assets and liabilities are reflected in OCI in order to minimise accounting mismatches between the accounting for financial assets and insurance assets and liabilities. The Company’s financial assets backing the personal accident insurance portfolios are predominantly measured FVOCI. For all other business, the Company does not disaggregate finance income and expenses because the related financial assets are managed on a fair value basis and measured at FVPL.

2.2.6.5. Net income or expense from reinsurance contracts held
The Company presents separately on the face of the statement of profit or loss and other comprehensive income, the amounts expected to be recovered from reinsurers, and an allocation of the reinsurance premiums paid. The Company treats reinsurance cash flows that are contingent on claims on the underlying contracts as part of the claims that are expected to be reimbursed under the reinsurance contract held, and excludes investment components and commissions from an allocation of reinsurance premiums presented on the face of the statement of profit or loss and other comprehensive income.
2.3. Financial assets

Commentary
For the purposes of these illustrative financial statements, it has been assumed that the Company has portfolios of non-complex, low risk financial assets.
The following illustrative disclosures are considered appropriate for the Company. Entities will need to ensure that their disclosures are specific to their individual circumstances and address the nature and terms of all relevant financial assets and liabilities held by an entity.

2.3.1. Initial recognition
The classification of financial instruments at initial recognition depends on their contractual terms and the business model for managing the instruments, as described in Notes 2.3.2.1.1 and 2.3.2.1.2.
Financial instruments are initially recognised on the trade date measured at their fair value (as defined in Note X). Except for financial assets and financial liabilities recorded at FVPL, transaction costs are added to this amount.

2.3.2. Measurement categories
The Company classifies all of its financial assets based on the business model for managing the assets and the asset’s contractual terms. The categories include the following:

- Amortised cost, as explained in Note 2.3.2.1
- FVOCI, as explained in Note 2.3.2.2
- FVPL, as explained in Note 2.3.2.3

2.3.2.1. Debt instruments measured at amortised cost
Debt instruments are held at amortised cost if both of the following conditions are met:

- The instruments are held within a business model with the objective of holding the instrument to collect the contractual cash flows
- The contractual terms of the debt instrument give rise on specified dates to cash flows that are solely payments of principal and interest (SPPI) on the principal amount outstanding

The details of these conditions are outlined below.

2.3.2.1.1. Business model assessment
The Company determines its business model at the level that best reflects how it manages groups of financial assets to achieve its business objective.

The Company holds financial assets to generate returns and provide a capital base to provide for settlement of claims as they arise. The Company considers the timing, amount and volatility of cash flow requirements to support insurance liability portfolios in determining the business model for the assets as well as the potential to maximise return for shareholders and future business development.

The Company's business model is not assessed on an instrument-by-instrument basis, but at a higher level of aggregated portfolios that is based on observable factors such as:

- How the performance of the business model and the financial assets held within that business model are evaluated and reported to the Company's key management personnel
- The risks that affect the performance of the business model (and the financial assets held within that business model) and, in particular, the way those risks are managed
- How managers of the business are compensated (for example, whether the compensation is based on the fair value of the assets managed or on the contractual cash flows collected)
- The expected frequency, value and timing of asset sales are also important aspects of the Company’s assessment

The business model assessment is based on reasonably expected scenarios without taking 'worst case' or 'stress case' scenarios into account. If cash flows after initial recognition are realised in a way that is different from the Company's original expectations, the Company does not change the classification of the remaining financial assets held in that business model, but incorporates such information when assessing newly originated or newly purchased financial assets going forward.

2.3 Financial assets (continued)
Notes to the Financial Statements

2.3.2.1. The SPPI test

As a second step of its classification process the Company assesses the contractual terms to identify whether they meet the SPPI test.

'Principal' for the purpose of this test is defined as the fair value of the financial asset at initial recognition and may change over the life of the financial asset (for example, if there are repayments of principal or amortisation of the premium/discount).

The most significant elements of interest within a debt arrangement are typically the consideration for the time value of money and credit risk. To make the SPPI assessment, the Company applies judgement and considers relevant factors such as the currency in which the financial asset is denominated, and the period for which the interest rate is set.

2.3.2.2. Debt instruments measured at fair value through other comprehensive income

The Company applies the new category under IFRS 9 for debt instruments measured at FVOCI when both of the following conditions are met:

- The instrument is held within a business model, the objective of which is both collecting contractual cash flows and selling financial assets
- The contractual terms of the financial asset meet the SPPI test

These instruments largely comprise debt instruments that had previously been classified as available-for-sale under IAS 39. Debt instruments in this category are those that are intended to be held to collect contractual cash flows and which may be sold in response to needs for liquidity or in response to changes in market conditions.

2.3.2.3. Financial assets measured at fair value through profit or loss

Financial assets in this category are those that are managed in a fair value business model, or that have been designated by management upon initial recognition, or are mandatorily required to be measured at fair value under IFRS 9. This category includes debt instruments whose cash flow characteristics fail the SPPI criterion or are not held within a business model whose objective is either to collect contractual cash flows, or both to collect contractual cash flows and sell.

2.3.3. Subsequent measurement

2.3.3.1. Debt instruments at amortised cost

After initial measurement, debt instruments are measured at amortised cost, using the effective interest rate (EIR) method, less allowance for impairment. Amortised cost is calculated by taking into account any discount or premium on acquisition and fee or costs that are an integral part of the EIR. ECLs are recognised in the statement of profit or loss when the investments are impaired.

2.3.3.2. Debt instruments at fair value through other comprehensive income

FVOCI debt instruments are subsequently measured at fair value with gains and losses arising due to changes in fair value recognised in OCI. Interest income and foreign exchange gains and losses are recognised in profit or loss in the same manner as for financial assets measured at amortised cost as explained in Note 2.4.1. The ECL calculation for debt instruments at FVOCI is explained in Note 2.3.6.2. Where the Company holds more than one investment in the same security, they are deemed to be disposed of on a first-in first-out basis. On derecognition, cumulative gains or losses previously recognised in OCI are reclassified from OCI to profit or loss.

2.3.3.3. Financial assets at fair value through profit or loss

Financial assets at FVPL are recorded in the statement of financial position at fair value. Changes in fair value are recorded in profit or loss. Interest earned on assets mandatorily required to be measured at FVPL is recorded using contractual interest rate, as explained in Note 2.4.2. Dividend income from equity instruments measured at FVPL is recorded in profit or loss as other operating income when the right to the payment has been established.
2.3 Financial assets (continued)

2.3.4. Reclassification of financial assets and liabilities

The Company does not reclassify its financial assets subsequent to their initial recognition, apart from the exceptional circumstances in which the Company acquires, disposes of, or terminates a business line.

IFRS 9.4.4.2
IFRS 9.B4.4.1

2.3.5. Derecognition

2.3.5.1. Derecognition other than for substantial modification

A financial asset (or, where applicable, a part of a financial asset or part of a group of similar financial assets) is derecognised when:

- The rights to receive cash flows from the asset have expired

Or

- The Company has transferred its right to receive cash flows from the asset or has assumed an obligation to pay the received cash flows in full without material delay to a third party under a ‘pass-through’ arrangement; and either: (a) the Company has transferred substantially all the risks and rewards of the asset; or (b) the Company has neither transferred nor retained substantially all the risks and rewards of the asset, but has transferred control of the asset.

The Company considers control to be transferred if and only if, the transferee has the practical ability to sell the asset in its entirety to an unrelated third party and is able to exercise that ability unilaterally and without imposing additional restrictions on the transfer.

When the Company has neither transferred nor retained substantially all of the risks and rewards and has retained control of the asset, the asset continues to be recognised only to the extent of the Company’s continuing involvement, in which case, the Company also recognises an associated liability. The transferred asset and the associated liability are measured on a basis that reflects the rights and obligations that the Company has retained.

Continuing involvement that takes the form of a guarantee over the transferred asset is measured at the lower of the original carrying amount of the asset and the maximum amount of consideration the Company could be required to pay.

IFRS 9.3.2.2
IFRS 9.3.2.3(a)
IFRS 9.3.2.3,(b)
IFRS 9.3.2.6
IFRS 9.3.2.9
IFRS 9.3.2.15
IFRS 9.3.2.16(a)

2.3.5.2. Derecognition due to substantial modification of terms and conditions

The Company derecognises a financial asset when the terms and conditions have been renegotiated to the extent that, substantially, it becomes a new instrument, with the difference recognised as a derecognition gain or loss. In the case of debt instruments at amortised cost, the newly recognised loans are classified as Stage 1 for ECL measurement purposes.

When assessing whether or not to derecognise an instrument, amongst others, the Company considers the following factors:

- Change in currency of the debt instrument
- Introduction of an equity feature
- Change in counterparty
- If the modification is such that the instrument would no longer meet the SPPI criterion

If the modification does not result in cash flows that are substantially different, the modification does not result in derecognition. Based on the change in cash flows discounted at the original EIR, the Company records a modification gain or loss.

IFRS 9.5.4.3
IFRS 9.B5.5.25-26
IFRS 9.5.4.3
2.3 Financial assets (continued)

2.3.6. Impairment of financial assets

Further disclosures relating to impairment of financial assets are also provided in the following notes:
- Impairment losses on financial instruments - Note 3.2.4.4
- Disclosures for significant judgements and estimates - Note 5.2.1

The Company recognises an allowance for ECLs for all debt instruments not held at fair value through profit or loss. ECLs are based on the difference between the contractual cash flows due in accordance with the contract and all the cash flows that the Company expects to receive, discounted at the appropriate effective interest rate.

ECLs are recognised in two stages. For credit exposures for which there has not been a significant increase in credit risk since initial recognition, ECLs are provided for credit losses that result from default events that are possible within the next 12-months (12-month ECL). For those credit exposures for which there has been a significant increase in credit risk since initial recognition, a loss allowance is required for credit losses expected over the remaining life of the exposure, irrespective of the timing of the default (a lifetime ECL).

The Company’s debt instruments comprise solely of quoted bonds that are graded in the top investment category (Very Good and Good) by the Euroland Credit Agency and, therefore, are considered to be low credit risk investments. It is the Company’s policy to measure ECLs on such instruments on a 12-month basis. Where the credit risk of any bond deteriorates, the Company will sell the bond and purchase bonds meeting the required investment grade.

2.3.6.1. The calculation of ECLs

The Company calculates ECLs based on scenarios to measure the expected cash shortfalls, discounted at an appropriate EIR. A cash shortfall is the difference between the cash flows that are due to the Company in accordance with the contract and the cash flows that the entity expects to receive.

When estimating the ECLs, the Company considers four scenarios (a base case, an upside, a mild downside and a more extreme downside). When relevant, the assessment of multiple scenarios also incorporates the probability that the defaulted loans will cure.

The mechanics of the ECL calculations are outlined below and the key elements are, as follows:
- **PD** The Probability of Default is an estimate of the likelihood of default over a given time horizon. It is estimated with consideration of economic scenarios and forward-looking information.
- **EAD** The Exposure at Default is an estimate of the exposure at a future default date, taking into account expected changes in the exposure after the reporting date, including repayments of principal and interest, whether scheduled by contract or otherwise, and accrued interest from missed payments.
- **LGD** The Loss Given Default is an estimate of the loss arising in the case where a default occurs at a given time. It is based on the difference between the contractual cash flows due and those that the Company would expect to receive. It is usually expressed as a percentage of the EAD.
### 2.3 Financial assets (continued)

The Company allocates its assets subject to ECL calculations to one of these categories, determined as follows:

- **12mECL**
  
  The 12mECL is calculated as the portion of long term ECLs (LTECLs) that represent the ECLs that result from default events on a financial instrument that are possible within 12 months after the reporting date. The Company calculates the 12mECL allowance based on the expectation of a default occurring in the 12 months following the reporting date. These expected 12-month default probabilities are applied to a forecast EAD and multiplied by the expected LGD and discounted by an appropriate EIR. This calculation is made for each of the four scenarios, as explained above.

- **LTECL**
  
  When an instrument has shown a significant increase in credit risk since origination, the Company records an allowance for the LTECLs. The mechanics are similar to those explained above, including the use of multiple scenarios, but PDs and LGDs are estimated over the lifetime of the instrument. The expected losses are discounted by an appropriate EIR.

- **Impairment**
  
  For debt instruments considered credit-impaired, the Company recognises the lifetime expected credit losses for these instruments. The method is similar to that for LTECL assets, with the PD set at 100%.

#### 2.3.6.2. Debt instruments measured at fair value through other comprehensive income

The ECLs for debt instruments measured at FVOCI do not reduce the carrying amount of these financial assets in the statement of financial position, which remains at fair value. Instead, an amount equal to the allowance that would arise if the assets were measured at amortised cost is recognised in OCI with a corresponding charge to profit or loss. The accumulated gain recognised in OCI is recycled to the profit or loss upon derecognition of the assets.

#### 2.3.6.3. Forward looking information

In its ECL models, the Company relies on a broad range of forward-looking information as economic inputs, such as:

- GDP growth
- Central Bank base rates

**Commentary**

The above inputs are general economic indicators that we have chosen for illustrative purposes only. In practice, further indicators such as commodity price inflation rates, currency exchange rates and government budget deficits may be used too.

The illustrative disclosure is provided on the assumptions:

- That it is the Company’s business model to invest in debt instruments that are quoted and that are graded in the top investment category
- Where the credit risk of any debt instrument deteriorates, the Company will sell the instrument and purchase instruments meeting the required investment grade

Entities will need to ensure that their disclosures adequately reflect the nature of ECL calculations relevant for its financial assets to comply with the requirements of IFRS 9.

#### 2.3.7. Write-offs

Financial assets are written off either partially or in their entirety only when the Company has stopped pursuing the recovery. If the amount to be written off is greater than the accumulated loss allowance, the difference is first treated as an addition to the allowance that is then applied against the gross carrying amount. Any subsequent recoveries are credited to credit loss expense. There were no write-offs over the periods reported in these financial statements.
2.4. Recognition of interest income

2.4.1. The effective interest rate method

Under IFRS 9, interest income is recorded using the effective interest rate (EIR) method for all financial assets measured at amortised cost. Similar to interest bearing financial assets previously classified as available-for-sale or held to maturity under IAS 39, interest income on interest bearing financial assets measured at FVOCI under IFRS 9 is also recorded using the EIR method. The EIR is the rate that exactly discounts estimated future cash receipts through the expected life of the financial asset or, when appropriate, a shorter period, to the gross carrying amount of the financial asset.

The EIR (and therefore, the amortised cost of the financial asset) is calculated by taking into account transaction costs and any discount or premium on acquisition of the financial asset as well as fees and costs that are an integral part of the EIR. The Company recognises interest income using a rate of return that represents the best estimate of a constant rate of return over the expected life of the debt instrument.

If expectations of a fixed rate financial asset’s cash flows are revised for reasons other than credit risk, and the changes to future contractual cash flows are discounted at the original EIR with a consequential adjustment to the carrying amount. The difference to the previous carrying amount is booked as a positive or negative adjustment to the carrying amount of the financial asset in the statement of financial position with a corresponding increase or decrease in interest income.

For floating-rate financial instruments, periodic re-estimation of cash flows to reflect the movements in the market rates of interest also alters the effective interest rate, but when instruments were initially recognised at an amount equal to the principal, re-estimating the future interest payments does not significantly affect the carrying amount of the asset or the liability.

2.4.2. Interest and similar income

Interest income comprises amounts calculated using the effective interest method and other methods. These are disclosed separately on the face of the income statement.

In its interest income calculated using the effective interest method the Company only includes interest on financial instruments at amortised cost or FVOCI.

Other interest income includes interest on all financial assets measured at FVPL, using the contractual interest rate.

The Company calculates interest income on financial assets, other than those considered credit-impaired, by applying the EIR to the gross carrying amount of the financial asset.
3. Insurance and financial risk

Commentary
The requirements to disclose information relating to the nature, timing and uncertainty of future cash flows that arise from insurance contracts are not new. Many similar insurance and financial (including credit, liquidity and market) risk disclosures were included in IFRS 4, often phrased to the effect that an insurer should make disclosures about insurance contracts, assuming that these were within the scope of IFRS 7. The equivalent disclosures now required by IFRS 17 are more specific to the circumstances of the measurement of insurance contracts in the standard, with no cross reference to IFRS 7.

There are a number of subtle differences between the new and existing disclosures, for example, IFRS 17.128(a)(ii) requires the sensitivity analyses for each type of market risk to be disclosed in a way that explains the relationship between the sensitivities to changes in risk exposures arising from insurance contracts and those arising from financial assets held. In addition, claims development figures must now be undiscounted, whereas IFRS 4 was silent on this.

In order to reflect overall financial risk disclosure for the Company, relevant disclosures from IFRS 7.31-42 have been presented alongside the IFRS 17 required disclosures in section 3.2 below.

Disclosures relevant to the impairment accounting under IFRS 9 for instruments held by the Company as required by IFRS 7.35A-N are illustrated in Note 3.2.4.3 below.

3.1. Insurance risk

3.1.1. Non-Life insurance contracts and reinsurance contracts

The Company principally issues the following types of non-life insurance contracts: personal accident; marine; property; and liability reinsurance.

For non-life insurance contracts, the most significant risks arise from climate changes, natural disasters and terrorist activities. For longer tail claims that take some years to settle, there is also inflation risk.

The objective of the Company is to ensure that sufficient reserves are available to cover the liabilities associated with these insurance and reinsurance contracts that it issues. The risk exposure is mitigated by diversification across the portfolios of insurance contracts. The variability of risks is also improved by careful selection and implementation of underwriting strategy guidelines, as well as the use of reinsurance held arrangements.

Furthermore, strict claim review policies to assess all new and ongoing claims, regular detailed review of claims handling procedures and frequent investigation of possible fraudulent claims are established to reduce the risk exposure of the Company. The Company further enforces a policy of actively managing and promptly settling claims, in order to reduce its exposure to unpredictable future developments that can negatively impact the business. Inflation risk is mitigated by taking expected inflation into account when estimating insurance contract liabilities and pricing appropriately.

The Company purchases reinsurance as part of its risk mitigation programme. Reinsurance held is placed on a proportional basis. Proportional reinsurance is quota-share reinsurance which is taken out to reduce the overall exposure of the Company to its marine business.

Amounts recoverable from reinsurers are estimated in a manner consistent with underlying insurance contract liabilities and in accordance with the reinsurance contracts. Although the Company has reinsurance arrangements, it is not relieved of its direct obligations to its policyholders and thus a credit exposure exists with respect to reinsurance held, to the extent that any reinsurer is unable to meet its obligations. The Company’s placement of reinsurance is diversified such that it is neither dependent on a single reinsurer nor are the operations of the Company substantially dependent upon any single reinsurance contract.

There is no single counterparty exposure that exceeds 5% of total reinsurance assets at the reporting date.

The following tables show the concentration of net insurance contract liabilities by type of contract:

3.1. Insurance risk (continued)

3.1.1.1. Sensitivities

The liability for incurred claims is sensitive to the key assumptions in the table below. It has not been possible to quantify the sensitivity of certain assumptions such as legislative changes or uncertainty in the estimation process.

The following sensitivity analysis shows the impact on gross and net liabilities, profit before tax and equity for reasonably possible movements in key assumptions with all other assumptions (refer Note 5.1.2) held constant. The correlation of assumptions will have a significant effect in determining the ultimate impacts, but to demonstrate the impact due to changes in each assumption, assumptions have been changed on an individual basis. It should be noted that movements in these assumptions are non-linear. The method used for deriving sensitivity information and significant assumptions did not change from the previous period.

**Commentary**

The impact of sensitivities to changes in discount rates is minimal due to the combination of:

- The liability for incurred claims for the portfolio included in property insurance product line not being discounted as claims are expected to be settled within a year
- The discount rate for liability for remaining coverage being set at the date of initial recognition remaining unchanged and therefore not subject to variation
3.1. Insurance risk (continued)

3.1.1.2. Claims development table

The following tables show the estimates of cumulative incurred claims, including both claims notified and IBNR for each successive accident year at each reporting date, together with cumulative payments to date.

As required by IFRS 17, in setting claims provisions, the Company gives consideration to the probability and magnitude of future experience being more adverse than assumed which is reflected in the risk adjustment. In general, the uncertainty associated with the ultimate cost of settling claims is greatest when the claim is at an early stage of development. As claims develop, the ultimate cost of claims becomes more certain.

The Company has not disclosed previously unpublished information about claims development that occurred earlier than five years before the end of the annual reporting period in which it first applies IFRS 17.

* For this product line there are no open claims for these accident years.

**Commentary**

The following should be noted in respect of the disclosure provided above:

1) The disclosure is provided for each product line in accordance with the Company’s decision to provide disaggregated disclosures on this basis.

2) The Company presents its claims development on an accident year basis as this is consistent with how the business is managed. IFRS 17 does not prescribe the format of the disclosure of claims development and the presentation of this information by underwriting or reporting year may also be permissible.

3) IFRS 17 specifically requires the previous estimates of amounts of claims to be presented on an undiscounted basis. IFRS 4 was silent regarding this.

4) The Company has elected to use the practical expedient for transition in IFRS 17.C28 to not disclose previously unpublished information about its claims development that occurred earlier than five years before the end of the annual reporting period in which it first applies IFRS 17.

5) For the Property insurance product line, for which uncertainty about the amount and timing of all claims payments is typically resolved within one year, the Company has not disclosed development information.
3.1. Insurance risk (continued)

6) For product lines with some longer tail claims, in respect of claims for which uncertainty about the amount and timing of the claims payments is typically resolved within one year, the Company has disclosed full development information. It could also be acceptable to not disclose the full information. It could also be acceptable to not disclose the full information and rather to include the related liability for incurred claims amount as a reconciling item. Entities should carefully consider which approach provides appropriate information for their users.

7) The tables are reflective of the complete balance of the liability for incurred claims, which may include claims handling costs and other incurred insurance expenses outstanding at year end. An entity may choose to exclude such other incurred insurance expenses from the main development disclosure, but include the amount as a reconciling item to the total of the liability for incurred claims balance.

8) Both gross and net claims development disclosure has been presented for illustrative purposes.

9) Amounts reflected are inclusive of the related risk adjustment. Alternatively, an entity may decide to present the tables excluding risk adjustment, and reflect the risk adjustment as a reconciling item.

10) IFRS 17.130 requires the reconciliation of the claims development disclosure with the aggregate carrying amount of the groups of insurance contracts, which an entity discloses applying paragraph 100(c). This is provided below the claims development table.

3.2. Financial risk

Commentary

The disclosure included below in respect of financial assets is considered appropriate given the non-complex lower risk financial assets held by the Company. Entities will need to ensure that their disclosures are specific to their individual circumstances and address the nature of risks and terms of all relevant financial assets and liabilities held.

3.2.1. Liquidity risk

Liquidity risk is the risk that the Company will encounter difficulty in meeting obligations associated with insurance liabilities that are settled by delivering cash or another financial asset. In respect of catastrophic events, there is also a liquidity risk associated with the timing differences between gross cash outflows and expected reinsurance recoveries.

The following policies and procedures are in place to mitigate the Company’s exposure to liquidity risk:

The Company’s liquidity risk policy sets out the assessment and determination of what constitutes liquidity risk for the Company. Compliance with the policy is monitored and exposures and breaches are reported to the Company’s risk committee. The policy is regularly reviewed for pertinence and for changes in the risk environment.

The Company maintains a portfolio of highly marketable and diverse assets that can be easily liquidated in the event of an unforeseeable interruption of cash flow. The Company also has committed lines of credit that it can access to meet liquidity needs.

3.2.1.1. Maturity profiles

Maturity analysis for insurance and reinsurance contract liabilities (present value of future cash flows basis)

The following table summarises the maturity profile of portfolios of insurance contracts issued that are liabilities and portfolios of reinsurance contracts held that are liabilities of the Company based on the estimates of the present value of the future cash flows expected to be paid out in the periods presented.

Commentary

IFRS 17.132 provides entities with two options for completing the maturity profile. The option that is not presented below is to provide an analysis of the remaining contractual undiscounted net cash flows. Entities should consider which is most appropriate to their user. The Company has provided an analysis of maturity profiles based on the estimates of the present value of future cash flows by estimated timing as it is in line with the Company’s current accounting policy and industry’s best practice.

The disclosure below only includes liabilities for incurred claims. As per IFRS 17.132(b), the inclusion of amounts for the liabilities for remaining coverage is not required. Due to the nature of the contracts held, there are no amounts relating to insurance contracts that are payable on demand. Therefore, no disclosure has been provided in respect of IFRS 17.132(c)

Commentary

IFRS 7.B11E requires an entity to disclose a maturity analysis of financial assets that it holds for managing liquidity risk (e.g., financial assets that are readily saleable or expected to generate cash inflows to meet cash outflows on financial liabilities) if that information is necessary to enable users of its financial statements to evaluate the nature and extent of liquidity risk.

Although this disclosure requirement is in respect of liquidity risk pertaining to financial liabilities, it has been included in this note, given that it is anticipated that this information is relevant for evaluating the nature and extent of liquidity risk relating to the Company’s insurance and reinsurance contract liabilities.

It should be noted that IFRS 17.132 provides two bases for reflecting maturity analyses for insurance and reinsurance contract liabilities (present value of future cash flows or undiscounted contractual maturity), whereas IFRS 7 only allows for undiscounted contractual maturity.

Current and non-current assets and liabilities

3.2. Financial risk (continued)

3.2.2. Market risk

Commentary

The sensitivity analysis required by IFRS 17.128(a)(ii) expands on the previous requirement of IFRS 4.39(d) by requiring the sensitivity analysis for each type of market risk to be disclosed in a way that explains the relationship between the sensitivities to changes in risk variables arising from insurance contracts and those arising from financial assets held by an entity.

IFRS 17.129 allows entities that use alternative methods to manage the sensitivity to risks arising from contracts within the scope of IFRS 17 to disclose such alternative sensitivities (similar to the provision in IFRS 4.39(d)(ii)). Further narrative information is also required to explain the method used to prepare such sensitivity, main parameters, assumptions, objective and any limitations. The use of alternative methods could result in inconsistencies between asset and liability information presented and reduce the usefulness of disclosure for users.

Market risk is the risk that the fair value or future cash flows of a financial instrument, insurance contract issued or reinsurance contract held will fluctuate because of changes in market prices. Market risk comprises three types of risk: foreign exchange rates (currency risk); market interest rates (interest rate risk); and market prices (price risk).

The Company’s market risk policy sets out the assessment and determination of what constitutes market risk for it. Compliance with the policy is monitored and exposures and breaches are reported to the Company’s risk committee. The policy is reviewed regularly for pertinence and for changes in the risk environment.

Guidelines are set for asset allocation and portfolio limit structure, to ensure that assets back specific policyholders’ liabilities and that assets are held to deliver income and gains needed to meet the Company’s contractual requirements.

The nature of the Company’s exposure to market risks and its objectives, policies and processes used to manage and measure the risks have not changed from the previous period.

3.2.2.1. Currency risk

Currency risk is the risk that the fair value of future cash flows of a financial instrument, insurance contract assets and/or liabilities will fluctuate because of changes in foreign exchange rates.

The Company’s principal transactions are carried out in euros and its exposure to foreign exchange risk arises primarily with respect to the US dollar. The Company’s financial assets are primarily denominated in the same currencies as its insurance contract liabilities.

The Company mitigates some of the foreign currency risk associated with insurance contracts by holding reinsurance contracts denominated in the same currencies as its insurance contract liabilities.
Notes to the Financial Statements

3.2. Financial risk (continued)

The table below summarises the Company’s financial assets and insurance contract assets and liabilities by major currencies:

</tbody>
</table>

The following analysis is performed for reasonably possible movements in key variables, with all other variables held constant, showing the impact on profit before tax and equity due to changes in the fair value of currency-sensitive monetary assets and liabilities, including those relating to insurance and reinsurance contracts. The correlation of variables will have a significant effect in determining the ultimate impact of currency risk, but to demonstrate the impact due to changes in variables, variables had to be changed on an individual basis. The method used for deriving sensitivity information and significant variables did not change from the previous period.

3.2.2.2. Interest rate risk

Interest rate risk is the risk that the fair value or future cash flows of a financial instrument or insurance contract or reinsurance contract will fluctuate because of changes in market interest rates.

Floating rate instruments expose the Company to cash flow interest risk, whereas fixed interest rate instruments expose the Company to fair value interest rate risk.

There is no direct contractual relationship between financial assets and insurance contracts. However, the Company's interest rate risk policy requires it to manage the extent of net interest rate risk by maintaining an appropriate mix of fixed and variable rate instruments to support the insurance contract liabilities. The policy also requires it to manage the maturities of interest bearing financial assets.
3.2. **Financial risk (continued)**

The Company has no significant concentration of interest rate risk.

The Company is exposed to interest rate risk through its debt instruments held and in respect of liabilities or assets for incurred claims where cash flows are not expected to be settled within a year from when claims are incurred. The Company's exposure to interest rate risk sensitive insurance and reinsurance contracts and debt instruments are, as follows:

<table>

### Commentary

In respect of insurance or reinsurance contract assets or liabilities for remaining coverage to which the PAA is applied:

- If at initial recognition, an entity expects that the time between providing each part of the services and the related premium due date is no more than a year apart, then the time value of money is not required to be taken into account

Or

- If this is not the case, then the liability or asset is calculated using a discount rate determined at initial recognition and, as such, the balance is not sensitive to movements in interest rates.

In respect of insurance or reinsurance contract assets or liabilities for incurred claims to which the PAA is applied:

- If cash flows are expected to be paid or received in one year or less from the date the claims are incurred, then the time value of money is not required to be taken into account

Or

- If this is not the case, then the liability or asset would be adjusted using a discount rate updated at each reporting period, therefore, resulting in the balance being sensitive to interest rate movements.

The following analysis is performed for reasonably possible movements in key variables with all other variables held constant, showing the impact on profit before tax and equity. The correlation of variables will have a significant effect in determining the ultimate impact of interest rate risk, but to demonstrate the impact due to changes in variables, variables have been changed on an individual basis. It should be noted that movements in these variables are non-linear. The method used for deriving sensitivity information and significant variables has not changed from the previous period.

#### 3.2.2.3. Price risk

Price risk is the risk that the fair value or future cash flows of financial instruments or insurance contract assets and/or liabilities will fluctuate because of changes in market prices (other than those arising from interest rate or foreign exchange rate risk), whether those changes are caused by factors specific to the individual financial instrument or contract, or by factors affecting all similar contracts or financial instruments traded in the market.

The Company’s price risk exposure relates to financial assets and financial liabilities whose values will fluctuate as a result of changes in market prices. The Company does not issue any participating contracts. Therefore, there are no insurance or reinsurance contracts which are exposed to price risk.

The Company’s price risk policy requires it to manage such risks by setting and monitoring objectives and constraints on investments, diversification plans, limits on individual and total equity instruments.

The Company has no significant concentration of price risk.

At the reporting date, the Company’s exposure to price risk is through equity investments held at fair value listed on the Euronext was €507,000 (2022: €902,000). Given that the changes in fair values of the equity investments held are strongly positively correlated with changes of the Euronext 100 market index, the Company has determined that an increase/decrease of 10% on the index could have an impact of approximately €50,700 (2022: €90,200) increase/decrease on the profit before tax and approximately €38,500 (2022: €68,700) increase/decrease on equity.

This analysis was performed for reasonably possible movements in the market index with all other variables held constant. The correlation of variables will have a significant effect in determining the ultimate impact on price risk, but to demonstrate the impact due to changes in variables, variables had to be changed on an individual basis. It should be noted that movements in these variables are non-linear. The method used for deriving sensitivity information and significant variables has not changed from the previous period.

#### Operational risks

Operational risk is the risk of loss arising from system failure, human error, fraud or external events. When controls fail to perform, operational risks can cause damage to reputation, have legal or regulatory implications or can lead to financial loss. The Company cannot expect to eliminate all operational risks, but by initiating a rigorous control framework and by monitoring and responding to potential risks, the Company is able to manage the risks. Controls include effective segregation of duties, access controls, authorisation and reconciliation procedures, staff education and assessment processes, including the use of internal audit. Business risks such as changes in environment, technology and the industry are monitored through the Company’s strategic planning and budgeting process.

#### Commentary

IFRS 7 and IFRS 17 do not specifically require disclosure of operational risk because it is not necessarily related to financial instruments or the amount, timing and uncertainty of future cash flows that arise from insurance and reinsurance contracts. The above narrative on operational risk is included for illustrative purposes only and does not cover all the possible operational risks for an insurer.
3.2. Financial risk (continued)

3.2.4. Credit risk

Commentary
The specific credit risk disclosures required by IFRS 17.121-126 and 131 along with disclosures relevant to the impairment accounting under IFRS 9 for instruments held by the Company as required by IFRS 7.35A-N are illustrated below.

In respect of the financial assets held by the Company, the following disclosures are considered appropriate given the non-complex lower risk financial assets held. Entities will need to ensure that their disclosures are specific to their individual circumstances and address the credit risk nature and terms of all relevant financial assets and liabilities held.

Credit risk is the risk that one party to a financial instrument, insurance contract issued in an asset position or reinsurance contract held will cause a financial loss for the other party by failing to discharge an obligation.

The following policies and procedures are in place to mitigate the Company's exposure to credit risk:

The Company's credit risk policy sets out the assessment and determination of what constitutes credit risk for the Company. Compliance with the policy is monitored and exposures and breaches are reported to the Company's risk committee. The policy is regularly reviewed for pertinence and for changes in the risk environment.

Credit risk relating to financial instruments is monitored by the Company's investment team. It is their responsibility to review and manage credit risk, including environmental risk for all counterparties. The Company manages and controls credit risk by setting limits on the amount of risk it is willing to accept for individual counterparties and for geographical and industry concentrations, and by monitoring exposures in relation to such limits. It is the Company's policy to invest in high quality financial instruments with a low risk of default. If there is a significant increase in credit risk, the policy dictates that the instrument should be sold and amounts recovered reinvested in high quality instruments.

Reinsurance is placed with counterparties that have a good credit rating and concentration of risk is avoided by following policy guidelines in respect of counterparties' limits that are set each year by the board of directors and are subject to regular reviews. At each reporting date, management performs an assessment of creditworthiness of reinsurers and updates the reinsurance purchase strategy.

The credit risk in respect of customer balances incurred on non-payment of premiums will only persist during the grace period specified in the policy document. Commission paid to intermediaries is netted off against amounts receivable from them to reduce the risk of default.

The nature of the Company's exposure to credit risk and its objectives, policies and processes used to manage and measure the risks have not changed from the previous period.

3.2.4.1. The Company's internal rating process

The Company's investment team prepares internal ratings for instruments held in which its counterparties are rated using internal grades (high grade, standard grade, sub-standard grade, past due but not impaired and individually impaired). The ratings are determined incorporating both qualitative and quantitative information that builds on information from Euroland Credit Agency, supplemented with information specific to the counterparty and other external information that could affect the counterparty's behaviour. These information sources are first used to determine whether an instrument has had a significant increase in credit risk.
Notes to the Financial Statements

3.2. Financial risk (continued)

The Company’s internal credit rating grades:

<table>
<thead>
<tr>
<th>Internal rating grade</th>
<th>Internal rating description</th>
<th>Euroland Credit Agency’s rating (when applicable)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-2</td>

<td>Individually impaired</td>
<td>Very bad</td>
</tr>
</tbody>
</table>

3.2.4.2. Credit exposure

The table below provides information regarding the credit risk exposure of the Company by classifying Very good+ as the highest possible rating. Assets that fall outside the range of Very good+ to Good are classified as non-investment grade. The amounts represent the maximum amount exposure to credit risk. The credit risk analysis below is presented in line with how the Company manages the risk. The Company manages its credit exposure based on the carrying value of the financial instruments and insurance and reinsurance contract assets.

The Company’s maximum exposure to credit risk from insurance contract assets issued is €8,000 (2022: €8,000)

The Company actively manages its product mix to ensure that there is no significant concentration of credit risk.
Notes to the Financial Statements

3.2. Financial risk (continued)

3.2.4.3. Impairment assessment

The Company’s ECL assessment and measurement method is set out below.

3.2.4.3.1. Significant increase in credit risk, default and cure

The Company continuously monitors all assets subject to ECLs. In order to determine whether an instrument or a portfolio of instruments is subject to 12mECL or LTECL, the Company assesses whether there has been a significant increase in credit risk since initial recognition.

The Company considers that there has been a significant increase in credit risk when any contractual payments are more than 30 days past due. In addition, the Company also considers a variety of instances that may indicate unlikeliness to pay by assessing whether there has been a significant increase in credit risk. Such events include:

- Internal rating of the counterparty indicating default or near-default
- The counterparty having past due liabilities to public creditors or employees
- The counterparty (or any legal entity within the debtor’s group) filing for bankruptcy application/protect
- Counterparty’s listed debt or equity suspended at the primary exchange because of rumours or facts about financial difficulties

The Company considers a financial instrument defaulted and, therefore, credit-impaired for ECL calculations in all cases when the counterparty becomes 90 days past due on its contractual payments. The Company may also consider an instrument to be in default when internal or external information indicates that the Company is unlikely to receive the outstanding contractual amounts in full. In such cases, the Company recognises a lifetime ECL.

In rare cases when an instrument identified as defaulted, it is the Company’s policy to consider a financial instrument as ‘cured’ and, therefore, re-classified out of credit-impaired when none of the default criteria have been present for at least twelve consecutive months.

There has been no significant increase in credit risk or default for financial assets during the year.

3.2.4.3.2. Expected credit loss

The Company assesses the possible default events within 12 months for the calculation of the 12mECL. Given the investment policy, the probability of default for new instruments acquired is generally determined to be minimal and the expected loss given default ratio assumed to be 100%.

In rare cases where a lifetime ECL is required to be calculated, the probability of default is estimated based on economic scenarios.

3.2.4.4. Impairment losses on financial investments subject to impairment assessment

3.2.4.4.1. Debt instruments measured at FVOCI

The table below shows the fair value of the Company’s debt instruments measured at FVOCI by credit risk, based on its internal credit rating system. Details of the Company’s internal grading system are explained in Note 3.2.4.1:

Commentary

In respect of the requirements of IFRS 7.35J, these illustrative disclosures assume that there were no modifications of contractual cash flows on financial assets. In respect of the requirements of IFRS 7.35K, these illustrative disclosures assume that there was no collateral held or other credit enhancements related to the debt instruments held by the Company. In respect of the requirements of IFRS 7.35L, these illustrative disclosures assume that there were no debt instruments written off by the Company in the periods disclosed.
4. Capital

4.1. Capital management objectives, policies and approach

The Company has established the following capital management objectives, policies and approach to managing the risks that affect its capital position:

- To maintain the required level of stability of the Company thereby providing a degree of security to policyholders
- To allocate capital efficiently and support the development of business by ensuring that returns on capital employed meet the requirements of its capital providers and shareholders
- To retain financial flexibility by maintaining strong liquidity and access to a range of capital markets
- To align the profile of assets and liabilities, taking account of risks inherent in the business
- To maintain financial strength to support new business growth and to satisfy the requirements of the policyholders, regulators and stakeholders
- To maintain strong credit ratings and healthy capital ratios in order to support its business objectives and maximise shareholders value

The Company is also subject to regulatory requirements within the jurisdictions in which it operates. Such regulations not only prescribe approval and monitoring of activities, but also impose certain restrictive provisions (e.g., capital adequacy) to minimise the risk of default and insolvency on the part of the insurance companies to meet unforeseeable liabilities as they arise.

The Company has met all of these requirements throughout the financial year.

In reporting financial strength, capital and solvency are measured using the rules prescribed by the Euroland Financial Services Authority (EFSA). These regulatory capital tests are based upon required levels of solvency, capital and a series of prudent assumptions in respect of the type of business written.

The Company’s capital management policy is to hold sufficient capital to cover the statutory requirements based on the EFSA directives, including any additional amounts required by the regulator.

In determining groups of contracts, the Company has elected to include in the same group contracts where the Company’s ability to set prices or levels of benefits for policyholders with different characteristics is constrained by regulation.

Approach to capital management

The Company seeks to optimise the structure and sources of capital to ensure that it consistently maximises returns to the shareholders.

The Company’s approach to managing capital involves managing assets, liabilities and risks in a coordinated way, assessing shortfalls between reported and required capital levels on a regular basis and taking appropriate actions to influence the capital position of the Company in the light of changes in economic conditions and risk characteristics. An important aspect of the Company’s overall capital management process is the setting of target risk adjusted rates of return, which are aligned to performance objectives and ensure that the Company is focused on the creation of value for shareholders.

The primary source of capital used by the Company is total equity. The Company also uses, where it is efficient to do so, sources of capital such as reinsurance, in addition to more traditional sources of funding.

The capital requirements are routinely forecast on a periodic basis and assessed against both the forecast available capital and the expected internal rate of return, including risk and sensitivity analyses. The process is ultimately subject to approval by the Board.

The Company has developed an Individual Capital Assessment (ICA) framework to identify the risks and quantify their impact on the economic capital. The ICA estimates how much capital is required to reduce the risk of insolvency to a remote degree of probability. The ICA has also been considered in assessing the capital requirements.

The Company has made no significant changes, from previous years, to its policies and processes for its capital structure.
Notes to the Financial Statements

4.1. Capital management objectives, policies and approach (continued)

Commentary

IAS 1.134 and IAS 1.135 require entities to make qualitative and quantitative disclosures regarding their objectives, policies and processes for managing capital. IAS 1.135(e) requires that if an entity has not complied with its externally imposed capital requirements, the consequence of such non-compliance must be disclosed. IFRS 17.126 requires entities to disclose the effect of the regulatory frameworks in which it operates; for example, minimum capital requirements or required interest-rate guarantees, which are similar to requirements under IAS1.134 and 1.135. Entities should disclose information based on the requirements of their regulatory framework.

The adjustments onto a regulatory basis represent assets inadmissible for regulatory reporting purposes.

5. Significant judgements and estimates

The key assumptions concerning the future and other key sources of estimation uncertainty at the reporting date, that have a significant risk of causing a material adjustment to the carrying amounts of assets and liabilities within the next financial year are discussed below. The Company based its assumptions and estimates on parameters available when the financial statements were prepared. Existing circumstances and assumptions about future developments, however, may change due to market changes or circumstances arising that are beyond the control of the Company. Such changes are reflected in the assumptions when they occur. The Company disaggregates information to disclose major product lines namely, marine, property, personal accident insurance and liability reinsurance issued. This disaggregation has been determined based on how the Company is managed.

5.1. Insurance and reinsurance contracts

The Company applies the PAA to simplify the measurement of insurance contracts. When measuring liabilities for remaining coverage, the PAA is broadly similar to the Company's previous accounting treatment under IFRS 4. However, when measuring liabilities for incurred claims, the Company now discounts cash flows that are expected to occur more than one year after the date on which the claims are incurred and includes an explicit risk adjustment for non-financial risk.

5.1.1. Liability for remaining coverage

Insurance acquisition cash flows

In the property insurance product line, the Company is eligible and chooses to recognise insurance acquisition cash flows as an expense immediately as incurred. This is because all insurance contracts issued within that product line have a coverage period of one year or less.

For personal accident insurance, marine insurance and liability reinsurance products, where groups are not eligible to recognise an expense immediately, insurance acquisition cash flows are allocated to related groups of insurance contracts recognised in the statement of financial position (including those groups that will include insurance contracts expected to arise from renewals). An asset for insurance acquisition cash flows is recognised for acquisition cash flows incurred before the related group of insurance contracts has been recognised.

The effect of electing to recognise insurance acquisition cash flows as an expense when incurred for a group of insurance contracts is to increase the liability for remaining coverage and reduce the likelihood of any subsequent onerous contract loss. There would be an increased charge to profit or loss on incurring the expense, offset by an increase in profit released over the coverage period.
5.1. Insurance and reinsurance contracts (continued)

Onerous groups
For groups of contracts that are onerous, the liability for remaining coverage is determined by the fulfilment cash flows. Any loss-recovery component is determined with reference to the loss component recognised on underlying contracts and the recovery expected on such claims from reinsurance contracts held.

Time value of money
For the marine and personal insurance product lines, the Company adjusts the carrying amount of the liability for remaining coverage to reflect the time value of money and the effect of financial risk using discount rates that reflect the characteristics of the cash flows of the group of insurance contracts at initial recognition.

5.1.2. Liability for incurred claims
The ultimate cost of outstanding claims is estimated by using a range of standard actuarial claims projection techniques, such as Chain Ladder and Bornheutter-Ferguson methods.

The main assumption underlying these techniques is that a Company’s past claims development experience can be used to project future claims development and hence ultimate claims costs. These methods extrapolate the development of paid and incurred losses, average costs per claim (including claims handling costs), and claim numbers based on the observed development of earlier years and expected loss ratios. Historical claims development is mainly analysed by accident years, but can also be further analysed by geographical area, as well as by significant business lines and claim types. Large claims are usually separately addressed, either by being reserved at the face value of loss adjuster estimates or separately projected in order to reflect their future development. In most cases, no explicit assumptions are made regarding future rates of claims inflation or loss ratios. Instead, the assumptions used are those implicit in the historical claims development data on which the projections are based. Additional qualitative judgement is used to assess the extent to which past trends may not apply in future, (e.g., to reflect one-off occurrences, changes in external or market factors such as public attitudes to claiming, economic conditions, levels of claims inflation, judicial decisions and legislation, as well as internal factors such as portfolio mix, policy features and claims handling procedures) in order to arrive at the estimated ultimate cost of claims that present the probability weighted expected value outcome from the range of possible outcomes, taking account of all the uncertainties involved.

Some of the insurance contracts that have been written in the property line of business permit the Company to sell property acquired in settling a claim. The Company also has the right to pursue third parties for payment of some or all costs. Estimates of salvage recoveries and subrogation reimbursements are considered as an allowance in the measurement of ultimate claims costs.

Other key circumstances affecting the reliability of assumptions include variation in interest rates, delays in settlement and changes in foreign currency exchange rates.

5.1.3. Discount rates
Insurance contract liabilities are calculated by discounting expected future cash flows at a risk free rate, plus an illiquidity premium where applicable. Risk free rates are determined by reference to the yields of highly liquid AAA-rated sovereign securities in the currency of the insurance contract liabilities. The illiquidity premium is determined by reference to observable market rates.

Discount rates applied for discounting of future cash flows are listed below:

5.1. Insurance and reinsurance contracts (continued)

Commentary

IFRS 17.117(b) requires entities to disclose any changes in methods and processes for estimating inputs used to measure insurance contracts. The reason of the change and type of contracts affected should be disclosed. For example, an entity may have changes in approach used to estimate the yield curve due to more market data or information becoming available.

5.1.4. Risk adjustment for non-financial risk

- The risk adjustment for non-financial risk is the compensation that the Company requires for bearing the uncertainty about the amount and timing of the cash flows of groups of insurance contracts. The risk adjustment reflects an amount that an insurer would rationally pay to remove the uncertainty that future cash flows will exceed the expected value amount.

- The Company has estimated the risk adjustment using a confidence level (probability of sufficiency) approach at the 75th percentile. That is, the Company has assessed its indifference to uncertainty for all product lines (as an indication of the compensation that it requires for bearing non-financial risk) as being equivalent to the 75th percentile confidence level less the mean of an estimated probability distribution of the future cash flows. The Company has estimated the probability distribution of the future cash flows, and the additional amount above the expected present value of future cash flows required to meet the target percentiles.

Commentary

The above example assumes the confidence level approach has been adopted to determine the risk adjustment. Other approaches may be adopted (e.g., a cost of capital approach).

5.1.5. Assets for insurance acquisition cash flows

The Company applies judgement in determining the inputs used in the methodology to systematically and rationally allocate insurance acquisition cash flows to groups of insurance contracts. This includes judgements about the amounts allocated to insurance contracts expected to arise from renewals of existing insurance contracts in a group and the volume of expected renewals from new contracts issued in the period.

At the end of each reporting period, the Company revisits the assumptions made to allocate insurance acquisition cash flows to groups and where necessary revises the amounts of assets for insurance acquisition cash flows accordingly.

In the current year, the Company revisited its inputs into its allocation methodology for the marine insurance product line and reduced the expected number of renewal contracts expected to be included in groups starting in 2025 and 2026. As a result, the assets for insurance acquisition cash flows for those groups were reduced, and allocations to 2024 groups were increased by €4,000. This change in allocation did not have an impact on current year profit or loss. In the prior year no changes were made.

Assets for insurance acquisition cash flows relating to the marine business were tested for impairment in the current year and a loss of €19,000 was recognised. No impairment was recognised in the prior year.

In the current and prior year, for other product lines, the Company did not identify any facts and circumstances indicating that the assets may be impaired.

5.2. Financial assets

5.2.1. Impairment losses on financial assets

The measurement of impairment losses under IFRS 9 across relevant financial assets requires judgement, in particular, for the estimation of the amount and timing of future cash flows when determining impairment losses and the assessment of a significant increase in credit risk. These estimates are driven by the outcome of modelled ECL scenarios and the relevant inputs used.
6. Insurance service expense

The breakdown of insurance service expenses by major product lines is presented below:

Notes:

a. The nature and amount of material expense included is disclosed in Note X.

Commentary

Although the disclosure of insurance service expense is not required by IFRS 17, it could give valuable information on reconciliation of the amount in statement of profit or loss and roll-forward of net asset or liability components of insurance liabilities in accordance with IFRS 17.100.

For the property insurance portfolios, the Company made an accounting policy choice to recognise insurance acquisition cash flows as an expense when incurred. Therefore, insurance acquisition cash flows for the portfolios are not included in the roll forward in Note 11.1.3, which is in line with Illustrative example 10 from Illustrative Examples for IFRS 17 Insurance Contracts.

The Company does not have any gains or losses arising from the derecognition of financial assets measured at amortised cost.
**Notes to the Financial Statements**

7. **Total investment income and net insurance financial result (continued)**

**Commentary**

The Company has disclosed finance income and expenses and the investment return on its assets in a tabular format. IFRS 17 does not require this level of detail; entities may provide qualitative notes disclosures as opposed to a detailed table to cover the requirement in IFRS 17.110 to explain the relationship between insurance finance income or expenses and the investment return on assets.

IFRS 7.20(a)(i) requires an entity to disclose separately gains and losses on financial assets designated FVPL upon initial recognition or subsequently and gains or losses on financial assets that are mandatorily measured at FVPL in accordance with IFRS 9. The illustrative example above contains only financial assets that are mandatorily measured at FVPL, therefore, a separate line was not required.

IFRS 17 requires insurers to account for and disclose the changes in the risk adjustment for non-performance of a reinsurer in respect of reinsurance contracts held in the notes to the financial statements. The Company defines credit risk as a financial risk as per Appendix A of IFRS 17. As such, the Company has chosen to disclose, the effects of non-performance for reinsurance held as part of finance costs under a separate line item. Entities may choose to present and disclose this in another section depending on their interpretation of the standard.

The breakdown of the assets by related insurance product line is presented below:

<table>
<thead>
<tr>
<th>In €000</th>
<th>Insurance related</th>
<th>Non-insurance related</th>
<th>Total</th>
</tr>
</thead>
<tbody>

<td>-</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>6,433</td>
<td>2,021</td>
<td>2,413</td>
</tr>
</tbody>
</table>

The Company manages separate asset portfolios to support the insurance contracts issued in each major product line.

**Commentary**

The above breakdown has been included to provide further insights for users of this publication. It is not a specific requirement of any standard, and it may or may not be relevant to an entity depending on how assets and liability portfolios are managed.
8. Equity and debt instruments at fair value through profit or loss

The breakdown of financial assets measured at FVPL is, as follows:

<table>
<thead>
<tr>
<th>In €000</th>
<th>31 December</th>
<th>1 January</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>2023</td>
<td>2022</td>
</tr>

<td>4,959</td>
</tr>
<tr>
<td><strong>Total debt instruments measured at FVOCI</strong></td>
<td><strong>11,356</strong></td>
<td><strong>10,688</strong></td>
</tr>
</tbody>
</table>

The loss allowance for debt investments at FVOCI of 62,000 (2022: 61,000) does not reduce the carrying amount of these investments (which are measured at fair value), but gives rise to an equal and opposite gain in OCI. IFRS 7.16A

10. Debt instruments measured at amortised cost

The breakdown of debt instruments measured at amortised cost is, as follows. For information relating to impairment refer to note 3.2.4.4.2.

<table>
<thead>
<tr>
<th>In €000</th>
<th>31 December</th>
<th>1 January</th>
</tr>
</thead>
<tbody>

11.1 Roll-forward of net asset or liability for insurance contracts issued showing the liability for remaining coverage and the liability for incurred claims

The Company disaggregates information to provide disclosure in respect of major product lines separately: personal accident insurance, marine insurance, property insurance and liability reinsurance issued. This disaggregation has been determined based on how the company is managed.

Commentary

IFRS 17.95 requires entities to aggregate or disaggregate information so that useful information is not obscured either by the inclusion of a large amount of insignificant detail or by the aggregation of items that have different characteristics. Entities need to apply judgement as to how, or even whether, they break down the required disclosures into separate lines of business or geographical areas. Examples of aggregation bases that might be appropriate for information disclosed about insurance contracts are listed by IFRS 17.96, as follows:

(a) Type of contract (for example, major product lines);
(b) Geographical area (for example, country or region); or
(c) Reportable segment, as defined in IFRS 8 Operating Segments.

Entities are not required to disaggregate information as disclosed in this publication but they need to apply judgement to aggregate or disaggregate information so that useful information is not obscured either by the inclusion of a large amount of insignificant detail or by the aggregation of items that have different characteristics. Once the decision for appropriate level of disaggregation is made, that IFRS 17 disclosures need to be provided separately for each unit of aggregation.
11.1. Roll-forward of net asset or liability for insurance contracts issued showing the liability for remaining coverage and the liability for incurred claims (continued)

11.1.1. Personal accident insurance

The roll-forward of the net asset or liability for insurance contracts issued, showing the liability for remaining coverage and the liability for incurred claims for personal accident insurance product line, is disclosed in the table below:

<table>

11.1. **Roll-forward of net asset or liability for insurance contracts issued showing the liability for remaining coverage and the liability for incurred claims (continued)**

Notes:
- a. Insurance acquisition cash flows were allocated on a straight-line basis during the coverage period of the respective group of contracts. Please see extracts from accounting policy for details on Note 2.2.5.5.
- b. The Company has made an accounting policy choice for the product line to disaggregate insurance finance expense between profit or loss and other comprehensive income. Please refer to Note 2.2.6.4 for details.
- c. Any refunds of premiums have been included in this line.
- d. Insurance acquisition cash flows paid after the related group is initially recognised are adjusted to the liability for remaining coverage. Insurance acquisition cash flows paid before the related group is recognised are included in assets for acquisition cash flows until the group is recognised.
- e. Other movements for acquisition cash flows include where a liability for insurance acquisition cash flows has been recognised when applying another IFRS standard.

**Commentary**

IFRS 17.100 requires entities to disclose movements in insurance contract liabilities and assets to show separately changes in liabilities for remaining coverage, loss component and liabilities for incurred claims. For insurance contracts to which the PAA approach has been applied, an entity should also disclose separately estimates of the present value of future cash flows and risk adjustment making up the liability for incurred claims. The movements are to be disclosed according to IFRS 17.103 and IFRS 17.105, and comprise amounts recognised in profit or loss and cash flows.

The roll-forward above includes the reconciliation from opening to closing balance in respect of assets for insurance acquisition cash flows required by IFRS 17 paragraphs 105A and 105B. An entity may choose to exclude this reconciliation from this table and present it as a separate roll-forward elsewhere.

The standard is silent on whether an entity should accrete interest on assets for insurance acquisition cash flows, as a result, entities have an accounting policy choice in this regard. In these disclosures, the Company has chosen not to accrete interest on assets for insurance acquisition cash flows.

Insurance revenue comprises the allocation of premiums to profit or loss on the basis of the passage of time or on the basis of the expected timing of incurred insurance service expenses. In the illustrative disclosures, allocation based on the passage of time was used.

Insurance claims and other expenses are represented by expected cash outflows on insurance events that have occurred.

Refunds of premiums have been included in the cash flow line for premiums received. An entity may also choose to include refunds of premiums together with investment components.

Changes to liabilities for incurred claims show changes in expected cash flows for insured events that have occurred and release of the risk adjustment.

Insurance finance expenses comprises accrual of interest on the net insurance liabilities. The change in discount rates is allocated to other comprehensive income for this product line. The contracts have a significant finance component which is incorporated into liability for remaining coverage.
11.1. Roll-forward of net asset or liability for insurance contracts issued showing the liability for remaining coverage and the liability for incurred claims (continued)

The expected timing of when assets for insurance acquisition cash flows will be derecognised and included in the measurement of the group of insurance contracts to which they are allocated is disclosed in the table below:

<table>
<thead>
<tr>
<th>Expected timing of derecognition of assets balance as at 31/12</th>

</tr>
</tbody>
</table>

Commentary
The above disclosure reflects to requirement to disclose quantitative information in appropriate time bands around when the Company expects to derecognise an asset for insurance acquisition cash flows. The Company considers the above time bands to be appropriate in respect of its products, however, entities should consider which is most appropriate to their business.
11.1. Roll-forward of net asset or liability for insurance contracts issued showing the liability for remaining coverage and the liability for incurred claims (continued)

11.1.2. Marine insurance

The roll-forward of the net asset or liability for insurance contracts issued, showing the liability for remaining coverage and the liability for incurred claims for marine insurance product line, is disclosed in the table below:

11.1. Roll-forward of net asset or liability for insurance contracts issued showing the liability for remaining coverage and the liability for incurred claims (continued)

Notes:

a. Insurance acquisition cash flows were allocated on a straight-line basis during the coverage period of the respective group of contracts. Please see extracts from the accounting policy for details on Note 2.2.5.5.

b. The Company has made an accounting policy choice for the product line to recognise net insurance finance expense in profit or loss only. Please refer to Note 2.2.6.4 for details.

c. Any refunds of premiums have been included in this line.

Commentary

Losses on onerous contracts are represented by the loss component recognised and partly reversed. In 2022, loss was recognised for one of the groups of contracts (group A) as it became onerous. In 2023, the insured event occurred, and the loss component was partly transferred to liability for incurred claims, the remaining part of the loss was reversed.

Insurance finance expenses comprise the accrual of interest on net insurance liabilities. The contracts are long term and have a significant finance component which is incorporated into liability for remaining coverage.

In the illustrative example above, several groups of contracts were issued in US dollars. The effect of changes in the exchange rate is reflected in the line “Effect of movements in exchange rates”. For the purpose of the example, we calculated figures in USD and then translated to EUR.

The expected timing for when assets for insurance acquisition cash flows will be derecognised and included in the measurement of the group of insurance contracts to which they relate is disclosed in the table below:

<table>
<thead>
<tr>
<th>Expected timing of derecognition of assets balance as at 31/12</th>

Notes:

a. The Company is not required to adjust future cash flows in liability for incurred claims for the time value of money and the effect of financial risk as, for the product line, those cash flows are expected to be paid in less than one year. Please refer to Note 2.2.5.3, for details.

b. Any refunds of premiums have been included in this line.

Commentary

An entity may choose to recognise insurance acquisition cash flows as expense when they occurred only if the coverage period is less than one year.
11.1. **Roll-forward of net asset or liability for insurance contracts issued showing the liability for remaining coverage and the liability for incurred claims (continued)**

**Notes:**

a. Insurance acquisition cash flows were allocated on a straight-line basis during the coverage period of the respective group of contracts. Please see extracts from the accounting policy for details on Note 2.2.5.5.

b. The Company has made an accounting policy choice for the product line to recognise net insurance finance expense in profit or loss only.

c. Any refunds of premiums have been included in this line.

d. Insurance acquisition cash flows paid after the related group is initially recognised are adjusted to the liability for remaining coverage. Insurance acquisition cash flows paid before the related group is recognised are included in assets for acquisition cash flows until the group is recognised.

e. 'Other movements' for assets for insurance acquisition cash flows include where a liability for insurance acquisition cash flows has been recognised applying another IFRS standard.

f. As at 31 December 2023 and 31 December 2022, all assets for insurance acquisition cash flows are expected to be derecognised within one year.
### 11.1. Roll-forward of net asset or liability for insurance contracts issued showing the liability for remaining coverage and the liability for incurred claims (continued)

**Commentary**

Insurance finance expenses comprise accrual of interest on liabilities for incurred claims. An entity is not required to adjust the liability for remaining coverage to reflect time value of money if the time between providing each part of the services and the related premium is no more than a year.

In the illustrative disclosure above, investment components represented by profit commission included in reinsurance contracts issued. Profit commission is closely related to reinsurance contracts issued and must not be separated, but will be shown in the separate line in the roll-forward for presentation purposes. The investment component will be excluded from insurance revenue and insurance service expenses as required by IFRS 17.85.

The Company has determined that it does not expect renewal insurance contracts to arise from new contracts written in the period, and as such it has disclosed in the notes above that all assets for insurance acquisition cash flows are expected to be derecognised within one year.

One portfolio includes reinsurance treaties where the premium is only due at the end of the coverage period. This has resulted in the portfolio being in a net asset position.
## 11.2. Roll-forward of net asset or liability for reinsurance contracts held showing the assets for remaining coverage and the amounts recoverable on incurred claims

### 11.2.1. Marine insurance

The roll-forward of the net asset or liability for reinsurance contracts held showing assets for remaining coverage and amounts recoverable on incurred claims arising on marine insurance ceded to reinsurers is disclosed in the table below:

<td></td>
<td>(IFRS 17.99(k))</td>
</tr>
</tbody>
</table>

**Notes:**

a. A loss-recovery component was set up upon the initial recognition of an onerous group of underlying insurance contracts. It has been subsequently reduced to zero in line with reductions in the onerous group of underlying insurance contracts in order to reflect that the loss-recovery component shall not exceed the portion of the carrying amount of the loss component of the onerous group of underlying insurance contracts that the entity expects to recover from the group of reinsurance contracts held.

b. The Company applies a consistent accounting policy to reinsurance contracts held and recognises net insurance finance expense in profit or loss only. Please refer to Note 2.2.5.4 for details.

c. During 2022, the rating of Reinsurer A decreased. The risk of non-performance for the reinsurer was reassessed and expected cash flows for the reinsurance contracts held with the reinsurer were changed.

The change in the expected cash flows related to the non-performance risk change was shown separately in the roll-forward.
11.2. **Roll-forward of net asset or liability for reinsurance contracts held showing the assets for remaining coverage and the amounts recoverable on incurred claims (continued)**

**Commentary**

Although the breakdown of amounts recoverable from reinsurers might not be directly required by IFRS 17.103(b), it could provide valuable information to users of financial statements on reinsurance contracts held results calculations.

The roll-forward for reinsurance contracts held required by IFRS 17.100 does not contain the column with the loss component as reinsurance contracts held cannot be onerous. A loss-recovery component column has been included to reflect amounts recognised in income where eligible reinsurance contracts cover onerous underlying contracts, and any subsequent reductions to such loss-recovery components.

For reinsurance contracts held to which the PAA approach has been applied, an entity must also disclose separately estimates of the present value of future cash flows and risk adjustment.

The roll-forward above shows the gross presentation of net income or expense from reinsurance contracts held. Though the presentation is not required by IFRS 17, it could be useful for the stakeholders to provide additional information similar to current reporting on reinsurance contracts held. An allocation of reinsurance premiums reconciles to an allocation of reinsurance premiums in the Statement of Comprehensive Income (gross presentation option as per IFRS 17.86). Amounts recoverable reconcile to the amounts recoverable in the Statement of Comprehensive Income.

Reinsurance finance income comprises accrual of interest on net reinsurance assets.
# Appendix 1 - Scope of the Publication

This publication contains disclosures required by IFRS 17 and only new and extended disclosures required by IFRS 7 Financial instruments: Disclosures (connected with the adoption of IFRS 9) considered relevant for insurers, accompanied by relevant accounting policies.

The summary of the disclosures required by IFRS 17 and IFRS 7 are presented below:

| IFRS 7.14, 15, 38 | **Collateral**
Disclose:
(a) the carrying amount of financial assets it has pledged as collateral for liabilities or contingent liabilities, including amounts that have been reclassified in accordance with paragraph 3.2.23(a) of IFRS 9; and
(b) the terms and conditions relating to its pledge. When collateral (of financial or non-financial assets) is held and the holder is permitted to sell or repledge the collateral in the absence of default by the owner of the collateral, disclose:
(a) the fair value of the collateral held;
(b) the fair value of any such collateral sold or repledged, and whether there is an obligation to return it; and
(c) the terms and conditions associated with its use of the collateral.
When financial or non-financial assets are obtained during the period by taking possession of collateral held as security or by calling on other credit enhancements (e.g., guarantees), and such assets meet the recognition criteria in other IFRSs, disclose for such assets held at the reporting date:
(a) the nature and carrying amount of the assets; and
(b) when the assets are not readily convertible into cash, its policies for disposing of such assets or for using them in its operations. | Existing | Not in scope of current publication (refer to current Good Insurance Note 28, 47) |

| IFRS 7.16A | The carrying amount of financial assets measured at fair value through other comprehensive income in accordance with paragraph 4.1.2A of IFRS 9 is not reduced by a loss allowance. The loss allowance shall not be presented separately in the statement of financial position as a reduction of the carrying amount of the financial asset, however it shall be disclosed in notes to the financial statements. | New | Debt instruments measured at fair value through other comprehensive income - Note 9 |

| IFRS 7.17 | If an instrument that contains both a liability and an equity component has been issued and it has multiple embedded derivatives whose values are interdependent (such as a callable convertible debt instrument), disclose the existence of those features. | Existing | Not in scope of this publication as considered unlikely for an insurer to regularly require this to be disclosed |

| IFRS 7.18-19 | **Defaults and breaches**
For loans payable recognised at the end of the reporting period, disclose:
(a) details of any defaults during the period of principal, interest, sinking fund, or redemption terms of those loans payable;
(b) the carrying amount of the loans payable in default at the end of the reporting period; and
(c) whether the default was remedied, or the terms of the loans payable were renegotiated, before the financial statements were authorised for issue. | Existing | Not in scope of this publication as considered unlikely for an insurer to regularly require this to be disclosed |

</tr>
</thead>
</table>
|            | (a) a maturity analysis for non-derivative financial liabilities (including issued financial guarantee contracts) that shows the remaining contractual maturities.  
(b) a maturity analysis for derivative financial liabilities. The maturity analysis shall include the remaining contractual maturities for those derivative financial liabilities for which contractual maturities are essential for an understanding of the timing of the cash flows (see paragraph B11B).  
(c) a description of how it manages the liquidity risk inherent in (a) and (b). | New/extended/existing | Existing | Financial risk - Note 3.2.2 |
| IFRS 7.40-42 | **Market risk**  
Disclose:  
(a) a sensitivity analysis for each type of market risk to which the entity is exposed at the end of the reporting period, showing how profit or loss and equity would have been affected by changes in the relevant risk variable that were reasonably possible at that date;  
(b) the methods and assumptions used in preparing the sensitivity analysis; and  
(c) changes from the previous period in the methods and assumptions used, and the reasons for such changes;  
Or if an entity prepares a sensitivity analysis, such as value-at-risk, that reflects interdependencies between risk variables (e.g., interest rates and exchange rates) and uses it to manage financial risks, disclose:  
(a) an explanation of the method used in preparing such a sensitivity analysis, and of the main parameters and assumptions underlying the data provided; and  
(b) an explanation of the objective of the method used and of limitations that may result in the information not fully reflecting the fair value of the assets and liabilities involved.  
When the sensitivity analyses disclosed in accordance with the above are unrepresentative of a risk inherent in a financial instrument (for example because the year-end exposure does not reflect the exposure during the year), disclose that fact and the reason that the sensitivity analyses are believed to be unrepresentative. | Existing | Not in scope of this publication as considered unlikely for an insurer to regularly require this to be disclosed |
| IFRS 7.42A-H | **Transfers of financial assets**  
Disclosure required for all transferred financial assets that are not derecognised and for any continuing involvement in a transferred asset, existing at the reporting date, irrespective of when the related transfer transaction occurred.  
An entity transfers all or a part of a financial asset (the transferred financial asset) if, and only if, it either:  
(a) transfers the contractual rights to receive the cash flows of that financial asset; or  
(b) retains the contractual rights to receive the cash flows of that financial asset, but assumes a contractual obligation to pay the cash flows to one or more recipients in an arrangement.  
An entity shall disclose information that enables users of its financial statements:  
(a) to understand the relationship between transferred financial assets that are not derecognised in their entirety and the associated liabilities; and  
(b) to evaluate the nature of, and risks associated with, the entity’s continuing involvement in derecognised financial assets. | New | Changes in accounting policies and disclosures - Note 1.1.3 |
| IFRS 7.42L-M, O,P | **Initial application of IFRS 9**

About EY
EY is a global leader in assurance, tax, strategy, transaction and consulting services. The insights and quality services we deliver help build trust and confidence in the capital markets and in economies the world over. We develop outstanding leaders who team to deliver on our promises to all of our stakeholders. In so doing, we play a critical role in building a better working world for our people, for our clients and for our communities.

EY refers to the global organization, and may refer to one or more, of the member firms of Ernst & Young Global Limited, each of which is a separate legal entity. Ernst & Young Global Limited, a UK company limited by guarantee, does not provide services to clients. Information about how EY collects and uses personal data and a description of the rights individuals have under data protection legislation are available via ey.com/privacy. For more information about our organization, please visit ey.com.

About EY's International Financial Reporting Standards Group
A global set of accounting standards provides the global economy with one measure to assess and compare the performance of companies. For companies applying or transitioning to International Financial Reporting Standards (IFRS), authoritative and timely guidance is essential as the standards continue to change. The impact stretches beyond accounting and reporting to the key business decisions you make. We have developed extensive global resources – people and knowledge – to support our clients applying IFRS and to help our client teams. Because we understand that you need a tailored service as much as consistent methodologies, we work to give you the benefit of our deep subject matter knowledge, our broad sector experience and the latest insights from our work worldwide.

WHAT DO WE KNOW ABOUT
MARKET DISCIPLINE IN INSURANCE?

MARTIN ELING

WORKING PAPERS ON RISK MANAGEMENT AND INSURANCE NO. 101

EDITED BY HATO SCHMEISER
CHAIR FOR RISK MANAGEMENT AND INSURANCE

NOVEMBER 2011
What Do We Know about Market Discipline in Insurance?

Martin Eling*

Abstract

The aim of this paper is to summarize the knowledge on market discipline in insurance and other financial service sectors. Market discipline can be defined as the ability of customers, investors, intermediaries (agents, brokers), and evaluators (analysts, auditors, rating agencies) to monitor and influence a company’s management. Looking at banking is especially interesting, since market discipline in this field has been studied extensively. Based on existing knowledge, we develop a framework for researching market discipline in insurance that includes its most important drivers and impediments. The results highlight a significant need for continuing research. The findings are of relevance not only for European insurers and regulators, but for institutions outside Europe.

1 Introduction

An important new dimension of the regulatory environment in banking and insurance is explicit reliance on market discipline. Market discipline—the influence of customers, investors, intermediaries (e.g., agents), and evaluators (e.g., rating agencies) on firm behavior—is a central element of both Basel II and Solvency II. Market discipline has been a perennial topic of research in the financial services sector since the 1970s (see Flannery, 2001). Likely due to the fact that Basel II has been in force for several years, most research into market discipline’s ability to regulate financial services has focused on banking (see, e.g., Martinez Peria and Schmukler, 2001; King, 2008), but some research has also been conducted for the insurance sector.1 Solvency II should add even more impetus to the study of market discipline. It is thus

* Martin Eling is professor of insurance management and director at the Institute of Insurance Economics at the University of St. Gallen, Kirchlistrasse 2, 9010 St. Gallen, Switzerland (martin.eling@unisg.ch). The author is grateful to Christian Biener, Dieter Kiesenbauer, Sebastian Marek, and Jan-Philipp Schmidt for helpful comments and suggestions. Special thanks to Peter Schlosser for his excellent research assistance.

1 Related papers, such as Harrington (2004, 2005) and Nocera (2005), will be discussed in detail throughout this paper. Another excellent introduction to market discipline in the German language is Hartung (2005). Furthermore, Solvency II’s approaching effective date has resulted in several recent empirical studies on market discipline in insurance (e.g., Eling and Schmit, 2011). Also, experimental evidence from behavioral insurance (Wakker, Thaler, and Tversky, 1997; Albrecht and Maurer, 2000; Zimmer, Schade, and Gründl, 2009; Zimmer, Gründl, and Schade, 2009) is relevant for market discipline. Furthermore, the European Commission conducted research when designing Solvency II (see CEIOPS, 2009 and other information on...
important to consider what is already known about market discipline in the insurance and related sectors.

To that end, this paper summarizes extant knowledge on market discipline in insurance and other financial services sectors. Looking at banking is especially interesting, since market discipline has been studied extensively in this field and much can be learned from that work. Based on existing knowledge, we develop a framework for researching market discipline in insurance that includes its most significant drivers and impediments. Our results also highlight a significant need for future research.

The results provide a clearer understanding of how market discipline works as a direct and indirect mechanism for monitoring and influencing by customers, investors, intermediaries, and evaluators. There are significant differences between banking and insurance with regard to market discipline. We also identify important differences between lines of business and legal forms in the insurance industry, which reveal that market discipline might be weak in some areas (e.g., in personal lines with complex products or with mutuals) and strong in others (e.g., in commercial lines or with stocks). We thus find a number of reasons why a “one-model-fits-all” approach might be inappropriate for market discipline in the insurance industry. The results of this analysis will be useful for insurers, regulators, and policymakers involved in revising regulatory standards both in Europe and in other markets. The article is not meant as an argument in favor of any particular type of regulation, but as an outline of potential impediments regulators may face in their efforts to enhance market discipline.

This paper is organized as follows. In Section 2 we review definitions and characteristics of market discipline that highlight differences between insurance and other financial services sectors. In Section 3 we take a look at the extant literature, especially that involving the banking field, and derive drivers of and impediments to market discipline in insurance. Section 4 concludes with potential policy implications and a summary of future research needs.2

2 Definition and measurement of market discipline

2.1 Definition of market discipline

There are several definitions of market discipline currently in use. For example, in the banking literature, there is widespread agreement that market discipline involves two distinct components (see Flannery, 2001; Bliss and Flannery, 2002, Forssbæck, 2009): (1) the ability of

---

2 Throughout this work, we analyze the role of both investors and customers in market discipline, instead of focusing on just one of these stakeholders; we also do not focus on any specific country. It is, however, important to keep in mind that differences across countries, such as governance mechanisms, insolvency experiences, and cultural norms, will affect the level of market discipline.
market participants to accurately assess the condition of a firm (monitoring) and (2) their ability to impact management action in a way that reflects that assessment (influencing). Market discipline thus has both an indirect and direct dimension (see Forssbæck, 2009). Monitoring captures the information aspect of market discipline, i.e., current and prospective bank claimants inform themselves about the bank’s condition and set prices for their claims accordingly. Influence refers to the mechanism by which banks, in order to avoid the adverse consequences of stronger discipline (such as higher financing costs and, ultimately, liquidity problems) decrease their risk exposure or avoid increasing it in the first place.\(^3\)

In the insurance field and with regard to the first component (monitoring), intermediaries (agents, brokers), evaluators (auditors, analysts, rating agencies), and regulators assess the financial strength and service quality of insurers. Due to the post-insolvency assessment funding mechanism of many guaranty funds and potential contagion effects of financial problems among insurers, insurers in selected lines also have an incentive to monitor each other (see Downs and Sommer, 1999). Overall, it thus seems that there are enough market participants willing to monitor risk taking in insurance. Guarantee schemes and the opaqueness of some insurers, however, could limit the willingness and ability to observe insurer behavior (see Lee, Mayers, and Smith, 1997; Babbel and Merrill, 2005; Pottier and Sommer, 2006; Zhang, Cox, and Van Ness, 2009).

The second component, influencing, is difficult to evaluate. The finance literature contains numerous reasons why we should be skeptical about the ability of market participants to influence managers (see Bliss and Flannery, 2002), including asymmetric information, costly monitoring, principal-agent problems, and conflicts of interest among stakeholders. Another impediment to market discipline is a legal environment that makes shareholder activism, e.g., a hostile takeover, difficult. From the shareholders’ perspective, monitoring and incentive contracts can be combined to mitigate the agency problem, and there are also other mechanisms that may induce managers to act in the shareholders’ best interests, such as reputational concerns, competitive labor markets, and the threat of takeover, dismissal, or bankruptcy (see Aggarwal and Samwick, 1999). The insurance sector has a number of characteristics that might limit the influencing component. For example, there is a relatively small risk of a bank run, at least in selected lines.\(^4\) Furthermore, especially in personal lines, individual policy-\(^3\) Compared to the neoclassical definition of market discipline in a complete and frictional market with symmetric information (leading to different willingness to pay depending on the default put option value; see Doherty and Garven, 1986), these definitions typically emphasize the aspect of asymmetric information, which is reduced by increasing market transparency.

\(^4\) In non-life insurance, payments are linked to claim events and insurers are funded in advance. In life insurance, surrendering a contract has disadvantages, such as lapse costs, and thus the policyholder has an incentive not to terminate the contract. See Eling and Schmeiser (2010). In countries with low lapse costs and higher mobility of capital, there could be a risk of an “insurance run,” at least in selected insurance sectors.
holders are relatively small in terms of contract volume, which limits their ability to affect decisions. It thus seems that the influencing component of insurance sector market discipline is not without difficulties and needs more study.

While most definitions of market discipline in the banking context include the monitoring and influencing components, Harrington (2004) and Nocera (2005) add another interesting dimension that is especially relevant in the insurance context. They differentiate between investor-driven market discipline, i.e. financial market discipline, and customer-driven market discipline, i.e. the extent to which demand by policyholders is sensitive to insolvency risk and thereby motivates insurers to manage their risk. In creating an insurance-specific definition of market discipline, it is also important to recognize the other monitoring and influencing elements (in addition to customers and investors), i.e., intermediaries (agents, brokers) and evaluators (analyst, auditors, rating agencies) that are involved in the buying decision. We thus define market discipline in the insurance sector as the ability of customers, investors, intermediaries, and evaluators to monitor and influence the management of insurance companies.

2.2. Measurement of market discipline

Table 1 contains a review of the different facets of market discipline and derives measures for quantifying it. Based on the definition developed in the last section, we distinguish between “direct” and “indirect” monitoring and influencing. While in theory, customers and investors directly influence management decisions, intermediaries and evaluators have both a direct and an indirect influence. For example, customers or investors react to market signals set by evaluators (e.g., changes in ratings) — a direct influence by customers; an indirect influence by evaluators. However, given that evaluators’ indirect influence can lead to direct influence by customers and investors, they might also have an opportunity to exert a direct influence themselves if, for instance, managers are keen to do anything possible to avoid a rating downgrade.

Table 1: Facets of market discipline

In the banking literature, investor-driven market discipline is usually studied either by analyzing stock prices or yields on debt instruments (see, e.g., Martinez Peria and Schmukler, 2001; DeAngelo, DeAngelo, and Gilson (1994) with regard to the collapse of First Executive in the United States in the early 1990s.
King, 2008). However, the insurance sector is different from the banking sector, especially as to business models and financing. Regarding legal form, in banking and insurance both, many companies are mutuals and many stock companies are not traded on the capital market. Furthermore, for many of the insurance companies that are traded on the stock exchange, there are no liquid markets, since only a small fraction of the stocks are in free float. Stock prices are thus of only limited use when evaluating risk sensitivity in insurance. Furthermore, the financing of insurers is different from that of other providers in the financial sector in that debt instruments typically are not traded (the reserves of the policyholders are the major debt instruments). The debenture spreads typically considered as market elements disciplining management behavior for the banking industry thus, for the most part, do not exist in the insurance industry.

An alternative way to measure market discipline is by looking at it as customer-driven. To this end, the studies on market discipline in insurance consider premium growth and lapse. Epermanis and Harrington (2006) and Eling and Schmit (2011) analyze premium growth around rating changes as a proxy for market discipline. Zanjani (2002) considers changes in lapse rates following rating changes. But there are also limitations in measuring customer-driven market discipline. For example, premiums are not the price of insurance, but the price times quantity. Typically, we cannot observe insurance prices, i.e., the premium rates per unit of coverage, and even if such information were available, it would be very difficult to compare insurers since the underlying expectations of claims costs used for calculating rates might be very different and are not observable (see Harrington, 2004). A proxy for insurance prices sometimes used in literature is the relation of insurer premiums to realized claims (see Sommer, 1996; Phillips, Cummins, and Allen, 1998).

From the above discussion, we conclude that in the insurance sector, market discipline focuses on the risk sensitivity of customer demand (for insurance coverage) and investor willingness to pay (for equity and debt). To measure market discipline, we thus need to identify market signals that affect the risk sensitivity of customers or investors. The second step is then to evaluate whether this signal has a significant impact on our measures of market discipline, i.e., demand and willingness to pay. Table 2 reviews a selection of potential signals.

---

5 Reinsurers are different from insurers in that many of them have stocks traded on capital markets. Furthermore, many large holdings, such as Allianz SE, are listed on the capital market. Overall, however, the number of liquid stocks is very limited. A broad empirical analysis based on stock prices is thus difficult.

6 There are some debt instruments, for example, credit-default swaps or hybrid instruments (e.g., participating certificates), but the number of observable instruments and the number of companies involved in such transactions is, again, very small. Catastrophe bonds or other forms of alternative risk transfer are not suitable since these are issued in special purpose vehicles and thus are not linked to the default risk of the sponsor.

7 There are other important differences between insurance and banking. For example, the insurer’s assets and liabilities are stochastic, particularly in the non-life sector. In banking, questions of duration (which do not play a large role in non-life insurance) and asset risk are the main risk factors. In life insurance, duration is also of high importance; additionally, insurers’ liabilities often embed many options and guarantees.
Market signal with regard to risk situation (input variable) | Signal given by (output variable) | Market reaction
---|---|---
Investor-driven market discipline
Annual and interim reports with outlook | Company | Investors’ willingness to pay reflected in Stock prices
Ad-hoc disclosure | Company | Bond yields
Director’s dealings | Company | Analysts’ comments
Analysts’ comments | Analysts | Company financial strength ratings | Rating agencies
Takeover bids | Competitor | Ad-hoc disclosure Company

Table 2: Measuring market discipline

Table 2 can be used to formulate hypotheses with regard to the disciplining impact. For example, we might expect that a better company rating has a positive influence on equity prices (i.e., an increase in price) and a negative influence on the debt yields (i.e., the spread over the risk-free interest rate decreases). We consider three main sources of market signals: the company, the evaluators (analysts, rating agencies), and the regulator (other sources of information such as consumer protection institutions or recommendations by friends are also important, but are not discussed in this paper). Table 2 also allows us to identify elements unique to the insurance sector that might be used to measure market discipline. Among these are product ratings, surplus participation, complaints, and other published statistics.

2.3. Discussion of market discipline in the context of other regulatory measures

Basel II and Solvency II are two examples of how market discipline research is relevant to regulatory problems. In both systems, market discipline is the third fundamental pillar. The expectation is that a transparent market will require less overt intervention by regulators as market participants themselves force appropriate firm behavior. The third pillar of Solvency II will be composed of public disclosure and reporting requirements that are intended to facilitate more rigorous and uniform analysis of capital adequacy across firms and across national borders. Improved market discipline is the hoped-for result. The extent to which market discipline can be relied on for successful regulation, however, depends on the strength of its influence.

Different mechanisms have been employed during the last decades in an effort to limit default probability in the financial services sector. Historically, solvency regulation focused on different types of safety nets, including deposit insurance schemes in banking (such as the Federal Deposit Insurance Corporation (FDIC) in the United States after the Great Depression) and guarantee funds in insurance. Until the early 1990s, many countries in the European Un-
ion addressed default risk by limiting competition via market entry restrictions and price and product regulation (see Eling, Klein, and Schmit, 2009). Rules for capital adequacy—imposing certain minimum capital requirements—one either an absolute or a risk-adjusted basis (e.g., Solvency I, U.S. RBC Standards) have also been introduced (see Eling, Schmeiser, and Schmit, 2007, for an overview).

None of these market interventions is without disadvantages. Safety nets can create moral hazard since the risk reduction the parties face leads them to take riskier actions or fail to take precautionary measures (see Demirgüç-Kunt and Detragiache 2002; De Ceuster and Masschelein, 2003). Distortions of competition, such as price and product regulation, decrease efficiency and limit innovation. Capital adequacy rules might be subject to adverse incentives, as illustrated in the recent financial crisis, e.g., by AIG and its credit default swap business, which was motivated by regulatory and rating arbitrage (see Eling and Schmeiser, 2010).

Recently, regulators have begun to incorporate a new market-based element into regulatory regimes by increasing transparency and disclosure requirements. Basel II’s inclusion of “market discipline” among its three regulatory pillars is the most notable example. Regulators see two main advantages to market discipline, which is, theoretically, brought into play by greater disclosure requirements. First, stakeholder monitoring should improve due to the availability of more information and, second, this improved monitoring is expected to influence insurer behavior, i.e., the stakeholders are expected to use their market power to influence management decisions with regard to risk taking.

Which of the different regulatory mechanisms is best is a question yet to be answered. In the case of Solvency II, regulators advocate a combination of capital adequacy (Pillar 1) and market discipline (Pillar 3). This provides the opportunity to integrate different approaches, but has several disadvantages too, one of which is cost: requiring insurers to employ extensive financial models (Pillar 1), as well as increased reporting requirements (Pillar 3), are both going to impose a substantial financial burden on insurers. The cost of regulation might outweigh its benefits. This argument is especially relevant for small insurers that might be pushed out of the market by requirements too costly to meet.

Market discipline cannot completely replace regulation. In a perfect and arbitrage-free market, where providers and policyholders have perfect information, one might argue that policyholders should be free to purchase insurance with a lower safety level as long as the contract pricing is fair, i.e., the net present value is zero (see Doherty and Garven, 1986; Gatzert and

---

9 There is no clear evidence as to whether the costs of Solvency II are higher than its benefits. The EU Commission demands an assessment of the costs of regulation for each new tool, including Solvency II. See, e.g., CEA (2007) for estimations of the administrative costs. Problems that arise are: (1) only direct costs (companies’ costs of implementation and future use) are considered and no indirect costs (inefficiency, effects on premiums and their result on other markets that depend on the insurance sector) and (2) potential benefits are described, but not quantified in any way.
Schmeiser, 2008). In this world, the policyholder, being fully informed, could choose to accept the default risk and hence there would be no need for capital regulation. However, in the insurance context, there is a “third-party problem”, i.e., the policyholder may cause an injury to a third party. This third party has no ex-ante contractual relationship with either the insurer or the policyholder, and hence cannot agree to some possibly low safety level in regard to the insurer’s default, with a consequent lower premium. In this situation, there is still a need for solvency requirements and regulation that cannot be replaced by enhanced market discipline per se.

Furthermore, there are interactions between the different pillars of Solvency II that need to be kept in mind when designing the regulation, especially regarding incentives. One important interaction is between the risk-based capital requirements in Pillar 1 and market discipline in Pillar 3. Under Pillar 3, insurance companies must publish their solvency testing results, thus informing the stakeholders and making the insurer’s safety level a competitive factor in the market. However, since internal risk models can be used for this purpose (as long as they are approved by the regulator), insurance companies may have an incentive to use internal models that “make them look safe” instead of models that would more accurately reflect their true risk situation (for a more detailed discussion on the pros and cons of internal models, see Eling, Schmeiser, and Schmit, 2007).

3 Evidence for market discipline (including facilitators and impediments)

We consider 62 peer-reviewed empirical studies on market discipline in financial services. For the field of insurance, we also include recent material presented at peer-reviewed conferences so as to increase the number of studies. Twenty of the 62 studies address the insurance industry; the other 42 studies are from the banking literature, reflecting the fact that, at least in terms of research questions and countries analyzed, more work has been done in banking field. However, as we highlight in the following discussion, some of the insights from the banking studies might be transferable to the insurance industry, e.g., with regard to safety nets.10

3.1. Evidence for market discipline in banking

There is a vast literature on market discipline, especially for the banking industry; research on the topic in this field dates back to the 1980s (see Table 3). The motivation for all this work is that innovation, e.g., in financial engineering, enabled financial intermediaries to become in-

10 The 16 oldest papers in banking are also summarized in Gilbert (1990). We also identified studies in other sectors of financial services, such as mutual funds (see, e.g., Dangl, Wu, and Zechner, 2008), but to reduce the complexity of the review, did not include them. Given the broadness of literature on market discipline in banking, we also cannot claim that our collection of 62 studies is complete, but we believe that the most important studies are included. Also note that experimental evidence, such as Wakker, Thaler, and Tversky (1997), is mentioned in our paper but is not included in the tables.
volved in complex financial operations that were very costly to monitor. Furthermore, exces-
sive risk taking in the 1980s resulted in the failure of some depository institutions, which
raised concern over safety and prompted calls for stricter regulation. Thus, by the 1980s,
banking regulators had market discipline on the policy agenda (see Park and Peristiani, 1988).
Research in this area was given another boost when market discipline was made one of the
three pillars of Basel II.

There are two main empirical results in regard to market discipline found in the banking liter-
ature. First, there is evidence of market discipline in banking over the last decades across a
variety of measures and countries, i.e., with regard to stock prices (e.g., Baer and Brewer,
1986), debt (Avery, Belton, and Goldberg, 1988; Sironi, 2003), and deposit growth (Park and
Peristiani, 1998).11 Second, investors in bank stocks have the strongest incentives to be risk
sensitive,12 while market discipline in debt is often hampered by safety nets. Safety nets of all
kinds create moral hazard and reduce market discipline (Billett, Garfinkel, and O’Neal, 1998;
Demirgüç-Kunt and Huizinga, 2004; Nier and Baumann, 2006). There is evidence that reduc-
ing safety nets increases market discipline (Flannery and Sorescu, 1996). A potential policy
implication is that regulators should enforce modifications of existing guarantee schemes to
bring market discipline into play. In this context, a number of authors (e.g., Benink and
Wihlborg, 2002) advocate for banks to issue a substantial amount of uninsured deposits in
order to enhance market discipline.

In addition to these two main results, we identify four other aspects from the banking litera-
ture that might be of relevance to the insurance industry. First, the strength of market disci-
pline depends on the line of business. Morgan and Stiroh (2001), e.g., show differences for
credit card, commercial, and industrial lending, all of which carry a penalty in terms of higher
spreads. Second, Sironi (2003) found differences depending on ownership structure, i.e., less
discipline was found for government-owned institutions. This is an important finding in light
of the traditional separation of stock, mutual, and public companies in the insurance industry
and the resulting differences in agency conflicts (see, e.g., Eling and Luhnen, 2010). Third,
Nier and Baumann (2006) emphasize that market discipline depends on the level of competi-
tion, i.e., market discipline is more effective in curbing the greater risk taking that arises in the
face of competition in those countries or industries where the competition is strong. Finally,

11 There are also authors who find no evidence of market discipline (Gorton and Santomero, 1990) but, com-
pared to the number of papers that do find such evidence, they are few in number. Of special relevance to
Solvency II because of the focus on European data is the work by Sironi (2003), who finds that European
banks’ debenture spreads reflect risk. More recently and also using European bank data, Distinguin, Rous,
and Tarazi (2006) observe that the accuracy of models in predicting bank financial distress through use of
stock market information depends on the extent to which bank liabilities are tradable. Models that account for
these nuances, therefore, will be more valuable.

12 In spite of their residual claimholder position and risk of total loss, this result is not trivial, since with limited
liability, equity holders might have an incentive to increase risk taking, as shown by Merton (1977). One
might thus argue that equity holders are less suitable monitors. Empirically, however, and also in more com-
plex theoretical models, this risk-increasing influence is not clear. See De Ceusters and Masschelein (2003).
Pop (2006) finds international differences in market discipline and argues that much work needs to be done, especially in Japan and certain European countries, to level the playing field so that market discipline can operate. Thus, there might be variation in the effectiveness of market discipline depending on the regulatory and cultural environment. The findings also highlight the potential for regulation to undermine market discipline (see, e.g., Billett, Garfinkel, and O’Neal, 1998).

Finally, it should be noted that almost all studies in the banking sector address the monitoring element of market discipline; that is, they test whether investors accurately understand changes in the firm’s condition and incorporate these into prices. Such testing, however, reveals nothing about the influencing component of market discipline, i.e., the response of firm managers to investor feedback. Bliss and Flannery (2002) is one of the few studies that directly measures this component by developing an influence regression using equity returns and expected managerial behavior. Their results show that market influence is weak. More research into the influencing component would be extremely useful.

3.2. Evidence for market discipline in insurance

Market discipline in insurance has not been as extensively researched as it has in the banking field and what work there is on the subject rarely employs non-U.S. data. Table 4 presents an overview of this research, dividing it into three categories: investor-driven market discipline (equity prices), customer-driven market discipline (price of insurance contracts, sum of premiums, number of contracts, lapse), and selected other aspects (impact of guarantee funds, studies on opaqueness).
Bank Equities and Investor Risk Perceptions: Potential Interactions of Market Efficiency and the International Debt Crisis

The reaction of bank stock prices to international debt crises and to the market efficiency in the banking sector is examined. The results suggest that the market efficiency does not fully reflect the information about the riskiness of bank stocks. The percentage of Latin American loans to total assets has a significant, negative impact on returns in 1982; energy loans had a negative impact on returns in the first half of the 1980s. The capital adequacy ratio is positively and significantly related to stock prices. Variability of stock prices helps explain CD rates; for the first time, the relationship between bank stock prices and CD rates is explained. The findings suggest that shareholders' risk-taking incentives were confined to a small fraction of highly risky institutions; even though shareholders have incentives to transfer wealth by pursuing riskier strategies, this risk taking is mostly outweighed by the possibility of losing charter value. The results support the hypothesis that SD investors are sensitive to bank risk, with the exception of SD issued by public sector banks, i.e., government-owned or guaranteed institutions. Sensitivity of SD spreads to measures of stand-alone risk has increased from the first to the second period. The results also support the hypothesis that SD investors are sensitive to bank risk, with the exception of SD issued by public sector banks, i.e., government-owned or guaranteed institutions. The results suggest that the market efficiency does not fully reflect the information about the riskiness of bank stocks. The findings suggest that shareholders' risk-taking incentives were confined to a small fraction of highly risky institutions; even though shareholders have incentives to transfer wealth by pursuing riskier strategies, this risk taking is mostly outweighed by the possibility of losing charter value. The results support the hypothesis that SD investors are sensitive to bank risk, with the exception of SD issued by public sector banks, i.e., government-owned or guaranteed institutions. Table 3: Results of literature review for banking (CD: certificate of deposit, J: journal, MD: market discipline, SD: subordinated debt) (continued)
Regarding the impact of rating changes on equity prices (investor market discipline), the early study by Singh and Power (1992) and the recent studies by Halek and Eckles (2010, 2011) find conflicting results. Singh and Power (1992) find no price reaction to rating changes, whereas Halek and Eckles (2010, 2011) document asymmetric responses (downgrades cut share prices, upgrades have little effect). Halek and Eckles (2010) attribute these differences to the structure of the ratings data, the event study methods, and the timing of the data. Other work on the impact of market signals on equity prices (Fenn and Cole, 1994; Brewer and Jackson, 2002) is more in line with Halek and Eckles (2010, 2011), so that overall it seems that there is evidence for market discipline in insurer stock prices.

The work on price of insurance offers implications rather than direct tests of market discipline. For example, studies from the 1990s (Sommer, 1996; Phillips, Cummins, and Allen, 1998; Cummins and Danzon, 1997) find a negative relationship between price proxies and firm risk in the property-casualty industry. This finding is consistent with market discipline, but as lower prices could also cause greater risk, it is difficult to identify the cause and effect relationship in this case. Also in a property-casualty context and using simple experiments, Wakker, Thaler, and Tversky (1997) show the risk sensitivity of policyholders in that an increase in default risk severely affects policyholder willingness to pay. Similar experimental evidence is found in Albrecht and Maurer (2000), Zimmer, Schade, and Gründl (2009), and Zimmer, Gründl, and Schade (2009). An important result of these studies is that in a transparent setting, market discipline will work, since knowing about differences in default risk severely affects policyholder behavior.

As to consumer influences, Zanjani (2002) uses A.M. Best ratings as a risk measure to study their relationship with life insurer lapse rates and finds some evidence of market discipline, with a positive relationship between risk (i.e., ratings) and lapse. Epermanis and Harrington (2006) consider insurer ratings in a property/casualty context and observe significant premium declines following rating downgrades, particularly for firms that had low ratings even before the downgrade. They also note the concentration of premium declines in commercial lines, which tend not to be protected by guarantee associations. In line with these findings for property-casualty insurance, Baranoff and Sager (2007) find that life insurance demand declines after a rating downgrade. Eling and Schmit (2011) confirm this finding for the German market. They find premium declines as well as increased lapse rates following rating downgrades. All these studies document asymmetric responses to positive and negative news.

Moreover, three studies from the 1990s (Lee, Mayers, and Smith, 1997; Brewer, Mondschean, and Strahan, 1997; Downs and Sommer, 1999) show that the establishment of guarantee funds increases risk taking. The establishment of guarantee funds might hamper risk sensitivity, especially that of policyholders.

Table 4: Results of literature review for insurance (J: journal, GIC: guaranteed investment contracts, MD: market discipline)
Recently, some studies have documented the opaqueness of insurers, which might limit the monitoring element of market discipline. For example, smaller insurers, stock insurers, insurers with greater stock investments, and more diversified insurers are, in general, more difficult to evaluate (see Pottier and Sommer, 2006). The willingness to monitor insurers might particularly depend on the line of business considered. Zhang, Cox, and Van Ness (2009) find evidence that differences among insurers in the opacity of lines of business (life vs. non-life, long vs. short tail) affect adverse selection for investors in the market for insurer equities, which should directly affect market discipline.

3.3. Derivation of trends, consensus, and notable conflicts in the subject areas

Looking at the relevant work published over the last few decades reveals that the definition of market discipline has evolved from simply considering the risk sensitivity of debt prices and spreads to accounting for the effects of this risk sensitivity on managerial decisions (see Covitz, Hancock, and Kwast, 2004). Market discipline is thus not an easy-to-measure one-dimensional construct, but is, instead, multifaced. These different facets are reflected in how market discipline is defined in the insurance context (see Section 2.1). Both in banking and insurance almost all studies focus on the monitoring component of market discipline, which is easier to measure than its influencing component (see Bliss and Flannery, 2002).

Overall, it appears that market discipline is reasonably strong in most insurance markets, but that there is some variation when it comes to legal form (Liu, Epermanis, and Cox, 2005), lines of business (Epermanis and Harrington, 2006), and countries (Eling and Schmit, 2011). All these results are confirmed on a broader empirical basis in the banking sector (see, e.g., Morgan and Stiroh, 2001; Sironi, 2003; Pop, 2006).

Moreover, and again for both banking and insurance, there appears to be a consensus that informational limitations and the regulatory environment play a major role in the level of market discipline, especially with regard to incentive conflicts between principals (stockholders, debtholders) and agents (managers). Agency problems are far stronger in those cases where market discipline is undermined by informational limitations. For example, agency effects are more common among mutual insurers, which generally have lower informational requirements than stock insurers. This result might be interpreted to mean that market discipline is an appropriate approach in some contexts, but that regulatory efforts will work better in others. In particular, regulatory efforts are likely more appropriate where informational limitations exist, while market discipline might be more effective when much information is available (see Eling and Schmit, 2011).

Another aspect is the asymmetry in findings regarding positive and negative news. The downside risk of sending a bad market signal is typically greater than the upside potential of a good market signal. Examples in the insurance sector are papers by Epermanis and Harrington
(2006), Baranoff and Sager (2007), and Halek and Eckles (2010). These results are consistent with those found in the finance literature on the effects of negative and positive news (see, e.g., Chan, 2003; Hong, Lim, and Stein, 2000).

There is thus a great deal of similarity between banking and insurance when it comes to findings from market discipline research. However, there are also notable differences between the two fields, especially regarding the relevance of debt instruments, which can be traced back to differences in the business models of these two financial institutions. For example, Zhang, Cox, and Van Ness (2009) discuss differences in opaqueness between banking and insurance that might affect market discipline. They argue that some sources of information opaqueness for banks and insurers are common, but that others are unique to insurers. In banking the liabilities are typically well-defined with respect to duration and amounts. In insurance there is greater asymmetric information because of the less certain duration of claim payments and the difficulty to predict loss amounts. Babbel and Merrill (2005) note in this context that the opaqueness and complexity of insurance contracts allow managers to create illusory values. Colquitt, Hoyt, and McCullough (2006) show that property-liability insurers are able to use greater discretion in setting loss reserves. Polonchek and Miller (1996) find greater information asymmetries with respect to the assets and liabilities of insurers compared to banks. Also Morgan (2002) provides evidence that insurers can be more opaque than banks, in his case considering disagreements among rating agencies.

Harrington (2005) directly compares market discipline in banking and insurance. He argues that market discipline is greater in insurance than in banking and concludes that capital requirements should be less stringent for insurers. Based on an analysis of risk sensitivity, buyer sophistication, search costs, and franchise value, he argues that overall market discipline is highest in reinsurance, moderate in life and non-life, and low in banking (see Table 1 in Harrington, 2005).

3.4. Derivation of facilitators and impediments to market discipline in insurance

The discussion has shown that market discipline is strongly affected by outside factors that can either facilitate or impede it. Recent government rescue efforts and direct intervention in the insurance and, especially, banking markets has created a great deal of distortion that has affected market discipline to a significant degree. These interventions give rise to some complicated, but highly interesting, questions involving moral hazard, the role of guarantee funds, the structure of rescue operations, the obligations of the firm being rescued, and the impact intervention has on competition. The most important impediments to market discipline in insurance are the following.

1. Work on banking finds that guarantee associations are an impediment to market discipline (see, e.g., Demirgüç-Kunt and Huizinga, 2004). Without guarantee schemes, bank manag-
ers have strong incentives to avoid risky loans and risky investments; however, mandated deposit insurance eliminates much of the risk involved in these activities. There are also several insurance studies that observe increased risk taking following the establishment of guarantee associations (see Lee, Mayers, and Smith, 1997; Downs and Sommer, 1999). One study also finds that risk levels increase when the amount of insurance sold increases in jurisdictions where guarantee associations exist (Brewer, Mondschean, and Strahan, 1997). These findings are in line with the expectation that the establishment of guarantee funds reduces monitoring incentives and thus negatively affects market discipline. There could thus be differences in market discipline between different lines of business or different regions, depending on the insurance guarantee fund design in place.

2. In addition to these direct market distortions, there might also be indirect or implicit market distortions. An example is bailout schemes, such as the “too-big-to-fail” concept, where governments feel obliged to rescue a troubled bank or insurer because they fear financial contagion.

3. The financial crisis revealed specific impediments to market discipline, e.g., the complexity of financial products. Financial institutions are often highly complex both in their ownership structure and in the nature of their business. For example, many insurers have dozens of reinsurance arrangements primarily intended to diversify risk, but these also reduce transparency and can sometimes mask financial problems (see Harrington, 2004).

4. Harrington (2004) mentions the judgment-proof problem as an impediment to market discipline. Under a compulsory insurance regime (e.g., auto liability, workers’ compensation, or professional liability), individuals with few assets to insure might simply buy the cheapest insurance they can find, with no regard to insolvency risk. The combination of compulsory insurance and judgment-proof buyers reduces the risk sensitivity of demand.

There are thus a number of reasons to expect differences in market discipline depending on the line of business. (1) The judgment-proof problem that arises in the case of compulsory insurance impedes market discipline. (2) Government or privately organized fund guarantees of all insurance claims and benefits destroy all incentives for market discipline. Reducing coverage, however, could be quite conducive to market discipline. (3) Differences in lines of business due to products and business complexity affect the degree of market discipline. Standardized products make it easier to identify differences between insurers, but this is more difficult when it comes to complex products and businesses. (4) An increase in financial leverage increases company risk. Life insurers typically have a much higher leverage than non-life insurers and this might affect the risk sensitivity of investors. (5) Market discipline could be stronger in commercial lines compared to personal lines. Policyholders in personal lines have less resources and competence (e.g., in terms of education to read financial reports) to
engage in efficient monitoring than do policyholders in commercial lines, which are usually larger and have more resources. On the other hand, personal line insurance decisions directly affect an individual’s own wealth, whereas commercial insurance decisions do not usually have much of a personal impact on the decision maker. This situation can create moral hazard problems, which lowers the efficiency of monitoring in commercial lines. Nonetheless, evidence indicates that market discipline in commercial lines is stronger than in personal lines (Epermanis and Harrington, 2006).

In this context, we would also expect more market discipline in reinsurance than in insurance because reinsurance covers only commercial business, while insurance covers both commercial and personal lines. An implication for policymakers is that when comparing personal and commercial insurance, it appears that market discipline is weak in some areas and strong in others.

This last point is also true when it comes to legal form. Insurers listed on the stock market are subject to more extensive reporting requirements than are mutual insurers. Liu, Epermanis, and Cox (2005) document that agency effects are more common among mutual insurers, which generally have lower informational requirements than do stock insurers. These results can be interpreted to mean that relying on market discipline is appropriate in some areas, but that formal regulation will work better in others. In particular, formal regulation is likely to be the more effective course in the presence of informational deficits (i.e., with mutuals). Market discipline will be more effective when information is generally available (i.e., with stocks).

When it comes to facilitating market discipline, the availability and quality of information is crucial. In this context, an important result from the experimental literature (Wakker, Thaler, and Tversky, 1997; Zimmer, Gründl, and Schade, 2009) is that if all necessary information is available, customers will discipline insurance companies by changing their demand. However, more information is not necessarily better information. In a theoretical world, Holmström (1979) shows that in moral hazard problems more information about the agent is never detrimental to the principal and, under mild assumptions, is always actually beneficial. In the “real” world, however, things can be quite different, especially when the cost of information is taken into consideration. Furthermore, more information can be useful only if it is consistently accessible and provided in a standardized form so that market participants can understand it and make appropriate comparisons between insurers. Standardization, consistency, and accessibility are thus important requirements for effective market discipline.

In conclusion, an effective market discipline framework needs to encompass the following. Stakeholders need to consider themselves at risk and they need to be able to observe risk efficiently, i.e., at reasonable costs. Reasons why risk sensitivity might be limited include guarantee schemes, anticipation of “too-big-to-fail” effects, compulsory insurance and judgment-
proof buyers, and product and business complexity. Even if stakeholders consider themselves at risk, monitoring will be hampered when the necessary information is too difficult and/or too costly to obtain. Furthermore, adverse selection could occur if some stakeholders have more information than others. Only if stakeholders consider themselves at risk and are able to observe risk efficiently will market discipline work. Market discipline will then manifest in either a reduction in willingness to pay (price effect) or in a reduction in demand for insurance from a particular provider (quantity effect). This might result in an influencing effect that can manifest directly, by managers shifting their risk exposure, or indirectly, by regulators acting on the signal.

4 Conclusions and future research
Market discipline focuses on the risk sensitivity of customer demand for insurance products and on investor willingness to pay for equity and debt. Evidence from the banking sector shows that market discipline can work very efficiently. However, the banking sector is different from the insurance sector in some aspects, so not all findings from banking may be generalizable to the insurance industry.

There are not enough insurance sector market discipline studies to conduct an in-depth impact assessment, but those that do exist indicate that market discipline appears to vary in terms of strength between the German insurance market (Eling and Schmit, 2011) and the U.S. market (Epermanis and Harrington, 2006). Furthermore, there are important drivers of (standardization and accessibility) and impediments to (market distortions such as guarantee funds) market discipline that regulators should keep in mind when attempting to enhance it. If market participants are not aware of risk and/or are unable to evaluate risk at a reasonable cost, there will be no market discipline.

There are many avenues future research can take. There is a great need for empirical tests of the risk sensitivity of policyholder demand, especially for countries other than the United States. Regarding potential investor-driven market discipline, it might be interesting to analyze spreads of credit default swaps, data that are available, at least for large insurers and reinsurers. For large insurers and reinsurers listed on stock markets, analyzing stock prices might be useful. It also would be interesting to see how risk sensitivity varies across countries, by comparing data from different regions and countries, and across different legal forms, by comparing mutual and stock insurer data. Such empirical tests could then be compared with results from other insurance and banking studies.

Another interesting task would be to measure the influence of market discipline in insurance with the methodology employed by Bliss and Flannery (2002). We also need more theoretical studies on market discipline in insurance, e.g., models that analyze the implications of market discipline on competition or models on the role of franchise value in insurance and how this is
affected by risk. These theoretical models could then be tested with empirical data to increase our knowledge of market discipline in the insurance industry.

Insurance Regulation in the United States and the European Union

A Comparison

Martin Eling, Robert W. Klein, and Joan T. Schmit

Executive Summary

In this paper we compare insurance regulatory frameworks in the United States (US) and European Union (EU), focusing primarily on solvency, but also considering product and price regulation, as well as other elements of consumer protection. This comparison highlights the use of more fluid and principles-based approaches in the EU as it is developing under Solvency II, while the US continues to focus essentially on static, rules-based regulation. The discussion further notes evidence suggesting that the EU approach is more successful in promoting a financially solid insurance sector.

Our analysis leads us to recommend that US regulators move toward a more comprehensive and integrated approach to assessing the financial risk of insurance companies. Such a move would incorporate greater emphasis on a flexible, principles-based system to include qualitative aspects, such as management assessment, while placing heavy emphasis on advanced quantitative methods. Among the more advanced methods that should be considered are enterprise risk management techniques that include tools such as dynamic financial analysis.

In the US, the states have indicated a desire to move toward a principles-based approach to financial regulation, but, at present, their specific initiatives are limited and the scope and pace of a broader restructuring of a state-based solvency framework is uncertain. Significant segments of the industry favor the creation of an optional federal charter (OFC) for insurance companies. It is quite possible that, under an OFC, the federal government would adopt a principles-based approach to insurance regulation consistent with the system being developed for banks under the Basel II accords. Indeed, the current financial crisis has added impetus to revamping the regulatory framework for all financial institutions, including insurance companies, but federalizing insurance regulation continues to face fierce political opposition from some groups. Hence, both in the US and in the EU, informed discourse will be essential to realizing the vision of a modern, efficient system for insurance regulation.

We argue in favor of a flexible scheme, where risk-based capital standards are used as guidelines—to assist insurers in managing their risk structures—rather than as absolute requirements (Eling et al. 2007). Flexibility is likely to yield a variety of risk strategies, limiting the possibility of systemic risk inherent in using a single standard model for all or even most insurers. Model arbitrage would be less effective, too, given that the requirements are flexible rather than rigid. US regulators are also encouraged to consider forming something similar to the Committee of European Insurance and Occupational Pension Supervisors (CEIOPS), which was created to redesign the EU regulatory framework. Currently CEIOPS is conducting public forums in which suggestions for future solvency rules are collected and discussed. In the US, the closest analog to a structure that would have any kind of real authority would be an interstate compact. This vehicle has been used to “harmonize” the regulation of life insurance products, and such a vehicle could be used to advance and harmonize other aspects of US insurance regulation.
Introduction

The United States (US) and the European Union (EU) offer an interesting and important contrast in their respective approaches to insurance regulation. In 1994, the EU enacted its first joint insurance regulations for member countries. Important elements of this first endeavor include pricing, products, and consumer protections. Solvency issues were formally addressed with the implementation of Solvency I in 2004—a set of rules focused mostly on minimum capital requirements. Following Basel II in the European banking industry, Solvency II will establish principles-based, risk-based capital standards when implemented, now scheduled for 2012. The lengthy and involved analysis phase associated with Solvency II, as well as the influence of insurers affected by it, has generated significant global interest. It may well be that Solvency II yields a model for international insurance regulation, particularly as we see movement toward international accounting standards. Insurance regulation in the US has been guided by a different philosophy, and this raises significant issues in terms of its place in the global marketplace.

The purpose of this paper is to present similarities and differences between the US and EU insurance regulatory frameworks, focusing primarily on solvency, but also extending to product, price, and other consumer protection elements. We discuss the pertinent elements of each system and review the literature that assesses their efficiency and effects on insurance markets. Our focus follows the current emphasis on solvency and enterprise risk management (ERM). First we review existing regulations and then discuss the details of the proposed Solvency II regulations. We also summarize the current knowledge about the effectiveness of various solvency regulations in limiting financial risk and insolvency costs, as well as other aspects of regulation. In some sense, our paper presents a contrast between the “old” and the “new” in insurance regulatory systems.

During the past fifteen years, most major economies around the globe have moved from fixed capital standards for their solvency regulation to some form of risk-based capital (RBC) standards. Canada and the US were among the first to introduce these risk-based standards, in 1992 and 1994 respectively. Japan followed with the “solvency margin standard” in 1996 and Australia with the “general insurance reform act” in 2001. Europe is relatively late in developing RBC requirements; however, some EU countries already have implemented first approaches: the United Kingdom (UK) introduced their concept of enhanced capital requirement and individual capital assessment in 2004, and Switzerland enacted the Swiss Solvency Test in 2006. Currently, the EU is working toward harmonizing risk-based methods across member countries, in what is known as Solvency II. The lengthy and involved analysis phase associated with Solvency II, as well as the influence of insurers affected by it, has generated significant global interest. It may well be that Solvency II yields a model for international insurance regulation, particularly as we see movement toward international accounting standards. Insurance regulation in the US has been guided by a different philosophy, and this raises significant issues in terms of its place in the global marketplace.
as well as the growing importance of international trade in insurance.

The research suggests that the type of regulatory standards and monitoring systems employed in the US are deficient and could be improved by using more advanced methods. The best systems appear to employ dynamic financial analysis, as well as qualitative methods that are more common in prudential frameworks. Hence, we may be able to use the US experience to anticipate how Solvency II will produce a better regulatory system. In turn, Solvency II may well offer insights that could be used to improve US regulation.

In reviewing recent regulatory solvency approaches and related literature, three main trends can be observed: (1) a movement toward an integrated total balance sheet approach that takes into account the interdependencies between assets and liabilities; (2) a greater focus on a flexible, principles-based setting instead of fixed rules (for example, many regulators allow the use of individual risk models instead of standard models to calculate the target capital requirements); and (3) the inclusion of qualitative aspects such as assessment of management in the regulatory framework. We will highlight these elements in our discussion.

Under Solvency II, insurance regulation is organized in three pillars. The first pillar addresses quantitative regulations for capital requirements. The second pillar focuses on the qualitative elements of supervision and incorporates regulatory principles on internal risk control, pricing, and product design. To the third pillar belong considerations about market transparency and disclosure requirements, which aim at promoting market discipline. Both the Basel II accords for banking regulation and the evolution of international insurance regulatory standards embrace the three-piller framework.

We follow the three pillars for our analyses of the US and EU insurance regulatory systems, first presenting the quantitative aspects and then following with the qualitative. We also discuss issues of market transparency, including an overview of product and price regulation as well as other elements of consumer protection. Empirical evidence of regulatory effects, particularly associated with solvency regulation, is also provided. Following this review of the US and EU systems, we present a discussion of differences and similarities. Because we hope that our monograph’s primary audience will be those in a position to affect insurance regulatory mechanisms, we conclude the paper with a discussion of policy implications and future research.

Insurance Regulation in the United States

Insurance regulation in the US has its historical origins in the early 1800s. While the regulation of other financial institutions has been largely federalized, insurance continues to be regulated by the states. The states each retain the principal responsibility for regulating insurance; the federal government has the authority to supersede state regulation when it chooses but has only done so selectively to date. Principal responsibility for the financial regulation of an insurer is delegated to its domiciliary state, but non-domiciliary states also perform some financial monitoring of all insurers licensed to operate in their jurisdictions and can suspend or revoke their licenses. Each state also retains the principal responsibility for regulating the market practices of all insurers licensed to operate in their jurisdictions and can suspend or revoke their licenses. Because we hope that our monograph’s primary audience will be those in a position to affect insurance regulatory mechanisms, we conclude the paper with a discussion of policy implications and future research.
The NAIC promulgates model laws and regulations, but the states are not required to enact them. In some areas, such as risk-based capital (RBC) standards, all the states have adopted NAIC model laws and related technical specifications. In many aspects of solvency regulation, the states have adopted uniform standards developed by the NAIC, but they may differ somewhat in terms of their specific rules. In the area of market regulation, there is much less uniformity, and the states may or may not use NAIC models or modify them according to their specific preferences. States may also adopt their own laws or regulations for which there is no related NAIC model.

It is important to understand the US philosophy and approach to insurance financial regulation, which contrast sharply with the EU paradigm. The states apply a prescriptive or rules-based approach to regulating insurers’ financial conditions and market practices that is oriented by an accounting perspective. This is reflected in numerous laws, regulations, rules, and other measures that govern virtually every aspect of insurers’ activities and financial structure. Regulators focus on insurers’ compliance with these prescriptions rather than the competence and prudence of their management and their overall financial risk. Insurers’ reported accounting values and financial statements are the principal measures by which their regulatory compliance is determined. This approach permeates all aspects of solvency oversight, including capital requirements.

In earlier times, the US paradigm might have been considered appropriate given the state of the science of financial risk analysis and management. However, in our opinion, it appears to be increasingly antiquated, inefficient, and potentially irrelevant in light of the evolution of the insurance industry and management methods. It is also lagging far behind the evolution of solvency oversight in the EU and the development of international standards. This raises serious concerns about the efficiency and effectiveness of US regulation. It also will have significant adverse implications for US insurers competing in a global marketplace.

The states have been slow to adopt anything resembling a principles-based approach (despite statements to the contrary), and this is unlikely to change without significant economic and/or political pressure or a regime change. To their credit, US regulators have sought to increase their emphasis on risk assessment within their monitoring systems and associated tools. For example, the NAIC created the Risk Assessment Working Group to guide the development of financial monitoring activities. It appears that examiners and analysts are encouraged to think about risk when they perform their tasks, but it is not clear what this means in a US context. The NAIC also has established the Principles Based Reserving Working Group to assess changes in policies and practices. The group has initially focused on principles-based reserve requirements for life insurance companies, but the group’s mandate is to ultimately expand its study to other aspects of regulating life-health and property-casualty insurance companies (NAIC 2008). Still, it is unclear as to how far and how fast US regulators would be willing to embrace a principles-based approach to insurer financial regulation. Without using dynamic financial analysis and employing other practices associated with a principles-based approach guided by a prudential philosophy, there are limits to what US regulators are likely to do in terms of true risk assessment.

Quantitative Regulations for Capital Requirements

The states impose two types of capital requirements on insurers. Each state has its own fixed-minimum requirement. Insurers are also subject to uniform RBC requirements based on a complex formula developed by the NAIC. There are different formulas for property-casualty, life, and
health insurers. An insurer is required to have capital that meets or exceeds the higher of the two standards. In the RBC formula, selected factors are multiplied times various accounting values (for example, assets, liabilities, or premiums) to produce RBC charges or amounts for each item. The charges are summed into several “baskets” and then subjected to a covariance adjustment to reflect the assumed independence of certain risks. The basic formula for property-casualty insurers is shown below:

\[ RBC = 0.5[R_0 + \sqrt{R_1^2 + R_2^2 + R_3^2 + R_4^2 + R_5^2}] \]

(components R1, R2, and R3) and insurance risks (components R4 and R5). There is also a component for the risk of default by affiliates and off-balance-sheet items, such as derivative instruments and contingent liabilities (R0). R1 accounts for the primary risks associated with fixed-income investments—the risk of default (that is, credit risk) and the risk of declines in asset values due to interest rate changes. In calculating R1 charges, assets are categorized by “credit quality,” and the factors applied vary inversely with quality. R2 models the risk associated with the decline in the values of other investments, such as stocks or real estate, and assigns selected factors. R3 accounts for the credit risk associated with reinsurance recoverables and other receivables. R4 reflects the risk associated with adverse loss reserve development, and different factors are assigned for different lines of business based on their historical loss development patterns. Finally, R5 accounts for “underwriting risk,” which is the risk that premiums collected in a given year may not be sufficient to cover the corresponding claims that arise from the business that is written. Different factors are also assigned in the R5 calculation for different lines of business based on historical loss ratios. The formula is much more complex than this simplified description indicates, but delving into its complexities is beyond the scope of this discussion.6

The covariance adjustment assumes that the R1 through R5 risks are independent but that the R0 risk is correlated with the other risks. This is an arbitrary assumption that is not necessarily consistent with reality (Butsic 1993). Multiplying the summed RBC amounts by 0.5 might raise the curiosity of some readers. This adjustment was simply intended to increase insurers’ reported RBC ratios. As discussed later, an RBC ratio of less than 200 percent requires “company action.” Hence, the operative RBC amount is twice the formula result, which negates the effect of the 0.5 adjustment in terms of regulatory compliance. The result is a framing issue and not a substantive outcome.

The RBC formulas for life and health insurers are similar, but they contain some differences to reflect the specific kinds of risks they face. The NAIC’s life RBC formula encompasses five major categories of risk: (1) asset risk—affiliates (C0); (2) asset risk—other (C1); (3) insurance risk (C2); (4) interest rate risk, health credit risk, and market risk (C3); and (5) business risk (C4). In 2005, the NAIC did adopt a modeling approach to assessing the market risk, interest rate, and expense-recovery risk of variable annuities that are reflected in the C3 component. Insurers can use prepackaged scenarios developed by the American Academy of
Actuaries or their own internal models. The RBC formula for health insurers includes: (1) asset risk—affiliates (H0); (2) asset risk—other (H1); (3) underwriting risk (H2); (4) credit risk (H3); and (5) business risk (H4).

An insurer's calculated risk-based capital (RBC) amount is compared to its actual total adjusted capital (TAC) to determine its RBC position. Under the RBC model law, certain company and regulatory actions are required if a company's TAC falls below a certain level of RBC. Four RBC levels for company and regulatory action have been established, with more severe action required for companies coming in at the lower levels (see Table 1). An insurer falling between the highest level (company action level) and the second-highest level (regulatory action level) is required to explain its financial condition and how it proposes to correct its capital deficiency to regulators. When an insurer slips below the second level, regulators are required to examine the insurer and institute corrective action, if necessary. Between the third level (authorized control level) and fourth level (mandatory control level), regulators are authorized to rehabilitate or liquidate the company. If an insurer's capital falls below the lowest threshold, regulators are required to seize control of the insurer.

The fact that an insurer's failure to meet specified RBC levels results in certain mandatory or authorized actions has important implications. For example, this limits a regulator's discretion to some degree. Arguably, this has contributed to regulators' caution in setting the RBC bar fairly low to avoid being compelled to take actions against an insurer that would not be warranted based on a more thorough and specific analysis of its financial condition and risk.

While there has been some tweaking of the RBC formulas over the years, some of their components and factors have not been modified since their original construction. For example, the property-casualty R4 and R5 factors have not been changed since the formula was developed in 1993. In September 2007, an American Academy of Actuaries committee presented its recommendations to the NAIC for updated and refined factors for reserving and underwriting risks (American Academy of Actuaries 2007).

The complexity of the US RBC formula gives a false sense of accuracy. Most important, the US RBC formula takes a static approach based on historical, reported accounting values. Unlike systems that use some form of dynamic financial analysis (DFA), it does not look forward to consider how an insurer might fare under a range of future scenarios. Regulators rejected proposals to incorporate DFA when the formulas were being developed. Also, accounting values can either be erroneous or manipulated to obtain more favorable regulatory assessments. For example, Cummins, Harrington, and Klein (1995) observe that the formula encourages insurers to lower their loss reserves to reduce the associated RBC charge. As noted later, similar issues have existed in the EU.

Further, while not all risks can be quantified, the formula omits some that can be, for example, operational risks, using methodological tools now

available. It is also important to note that the US RBC formula contains no explicit adjustment for an insurer’s size or its catastrophe exposure. Factors for both were proposed in the initial development of the property-casualty RBC formula but were rejected. The NAIC is currently considering adding a catastrophe component to RBC, but this initiative is bogged down in a debate that is unlikely to be resolved any time soon.

The US RBC formula could benefit from using better methods to model some of the risks the formula attempts to measure or from developing improved factors for the formula. Yet, while some elements of the formula could be improved, a more fruitful strategy would be to move toward some form of dynamic analysis that is tailored for a particular insurer’s characteristics. Of course, there are limits to what any kind of quantitative methods can reveal, which underlines the importance of qualitative assessments in the overall solvency monitoring process. Such factors would include management competence, corporate governance, and internal risk management (Conference of Insurance Supervisory Services of the Member States of the European Union 2002).

Qualitative and Other Elements of Supervision

Capital standards are only one component of an extensive framework for the financial supervision of US insurers. This framework includes detailed rules governing virtually all aspects of insurers’ financial structures and transactions, substantial financial reporting requirements, extensive monitoring, intervention against troubled insurers, receiverships, and insolvency guaranty associations. Here we primarily focus on the system of financial monitoring that augments capital standards and how regulators deal with companies that are in “hazardous financial condition.” While many of these elements might not be normally associated with the second pillar of solvency regulation, they play an important role in augmenting capital standards in the US.

One element of US insurance regulation that is receiving considerable attention is the accounting treatment of reinsurance purchased from non-US reinsurers. Under current statutory accounting rules, non-US reinsurers must post collateral in order for US insurers to receive accounting credit for the risk transferred. The current US rules have been criticized for being unreasonable and inefficient (Cummins 2007). After a long debate, the NAIC recently adopted a new framework for determining reinsurers’ collateral requirements. Under this new framework, US insurers may qualify as “national reinsurers” regulated by their home state. Non-US reinsurers may qualify as “port of entry” (POE) reinsurers by using an eligible state as a port of entry. A POE reinsurer will be subject to oversight by its port of entry supervisor. Both national reinsurers and POE reinsurers will be subject to collateral requirements that will be scaled according to something resembling a financial strength rating. Reinsurers receiving the highest rating will not be required to post collateral. US and non-US reinsurers that do not become qualified as national or POE reinsurers will remain subject to current state laws and regulations governing credit for reinsurance. An NAIC Reinsurance Review Supervision Division (RRSD) will be established to implement the new framework, including determining those states that will qualify as the supervisors for national and POE reinsurers.

Issues such as the treatment of foreign reinsurance become intertwined with solvency monitoring and regulators’ assessment of an insurer’s financial condition. Fundamentally, the objective of solvency monitoring is to ensure that insurance companies meet regulatory standards and to alert regulators if actions need to be taken against a company to protect its policyholders. Solvency
monitoring encompasses a broad range of regulatory activities, including financial reporting, early-warning systems, financial analysis, and examinations. In the US, insurers file annual and quarterly financial statements, which serve as the principal sources of information for the solvency monitoring process, but a number of other special reports are filed and used in regulatory monitoring. Accounting rules take on added importance because accounting values become the principal measures that determine whether an insurer is complying with regulatory standards. Regulators also have broad authority to compel insurers to provide other information deemed necessary to assess their financial condition.

The reports filed by insurers are subject to a “bench,” or “desk,” audit by an in-house financial analyst or examiner who assesses the information’s accuracy and reasonableness and determines whether an insurer requires further investigation. Typically, an insurer’s domiciliary regulator performs the most extensive review of its financial information, but an insurer must file financial reports with every state in which it is licensed, and non-domiciliary regulators also may review these reports. Additionally, the NAIC scrutinizes insurers’ financial statements and disseminates its analysis to state insurance departments. This reflects the multilayered nature of financial regulation and monitoring of US insurers—the domiciliary regulator constitutes the first layer, and non-domiciliary regulators and the NAIC constitute successive layers. Some might question whether this multilayered regulation and monitoring is redundant, but in the US system it is viewed as essential to assure that domiciliary regulators are taking appropriate actions against insurers in financial distress.

US regulators rely heavily on early-warning systems and other financial analysis tools in their monitoring activities. The fact that RBC standards are relatively low make financial monitoring particularly important because an insurer could be in financial distress and still exceed its RBC requirement. For the most part, these systems and tools are based on static, quantitative financial ratios. There is some use of qualitative information, but this appears to be limited and also may vary among the different states. The linchpins of US monitoring are the Insurance Regulatory Information System (IRIS) and the Financial Analysis Solvency Tools (FAST) system. IRIS is comprised of twelve to thirteen financial ratios (depending on the type of insurer), and its results are made available to the public. Normal ranges are set for each ratio. Ratio results that fall outside these ranges and other criteria can trigger further regulatory investigation.

In the early 1990s US regulators concluded that IRIS was inadequate, which led to the development of the FAST system. In the NAIC’s explanation of its systems, FAST comprises the full array of its solvency monitoring tools (including IRIS), but its heart is a computerized analytical routine called the “scoring system.” The scoring system consists of a series of approximately twenty financial ratios based on annual and quarterly statement data, but, unlike the IRIS ratios, it assigns different point values for different ranges of ratio results. A cumulative score is derived for each company, which is used to prioritize it for further analysis. These scores are provided to all regulators but are not available to the public.

Importantly, NAIC analysts use these scores and other information to identify companies that deserve special attention. This can lead to a process in which the NAIC’s Financial Analysis Working Group will query a domiciliary regulator about a company’s status and steps being taken to address any problems it may have. If the NAIC group determines that a domiciliary regulator is taking all appropriate actions, then the group will either close the file or continue to monitor the company. If the working group determines otherwise, it can com-
pel the domiciliary regulator to take the actions the
group deems necessary. The working group’s power
does not stem from any direct regulatory authority.
Rather, its power stems from the authority of non-
domiciliary regulators to suspend or terminate an
insurer’s license to write business in their jurisdic-
tions. This could effectively force the domiciliary
regulator’s hand, as license suspensions and termi-
nations would quickly lead to a company’s demise
and propel it into receivership.

Regulators use additional tools and informa-
tion in their financial monitoring activities. They
can use the NAIC’s “Insurer Profiles System” and
may also develop their own customized financial
ratios. Both periodic (every three to five years)
and targeted company financial examinations are
conducted; targeted exams are performed to address
specific questions or concerns that arise from
bench audits and analysis. Additional sources of
information may be tapped, including Securities
and Exchange Commission (SEC) filings, claims-
paying ability ratings, complaint ratios, market
conduct reports, correspondence from competi-
tors and agents, news articles, and other sources
of anecdotal information. While a wide array of
information sources are available, it appears that
US regulators rely primarily on quantitative data
and tools, as well as financial examinations. This
is consistent with a prescriptive, rules-based ap-
proach as most rules are stated in quantitative
terms. Importantly, US regulators tend not to
engage in consultations with an insurance com-
pany’s management to assess its competence and
future plans. Further, regulators do not perform
any kind of dynamic financial analysis nor require
companies to do so.

There are two categories of regulatory actions
with respect to troubled companies: (1) actions
to prevent a financially troubled insurer from be-
coming insolvent and (2) delinquency proceed-
ings against an insurer for the purpose of conserv-
ing, rehabilitating, reorganizing, or liquidating
the company. Actions within the first category in-
clude hearings and conferences, corrective plans,
restrictions on activities, notices of impairment,
cease and desist orders, and supervision. Some of
these actions may be conducted informally; others
require formal measures. Similarly, some actions
against companies may be confidential, and oth-
ers may be publicly announced. Regulators can
negotiate sales or mergers of troubled insurers in
order to avoid market disruptions. This is often
more feasible for life-health insurers because of
the embedded value of their long-term contracts.

If preventive regulatory actions are too late
or are otherwise unsuccessful and an insurer be-
comes severely impaired or insolvent, then formal
delinquency proceedings will be instituted. These
measures can encompass conservation, seizure of
assets, rehabilitation, liquidation, and dissolution.
For many insurers, these actions are progressive. A
regulator may first seek to conserve and rehabili-
tate a company to maintain availability of cover-
age and to avoid adverse effects on policyholders
and claimants, as well as lower insolvency costs.
The regulator, however, ultimately may be forced
to liquidate and dissolve the company if rehabili-
tation does not prove to be feasible. This is often
the case with property-casualty insurers that have
already dug themselves into a deep hole by the
time regulators seize control.

One question that is difficult to answer is how
much leverage regulators can exercise in compel-
lng an insurer to lower its financial risk if it greatly
exceeds its RBC requirement and complies with
all regulations from a quantitative perspective. In
theory, regulators can act against any company
deemed to be in “hazardous financial condition.”
However, regulators would bear the burden of
proof if an insurer resisted corrective action that
ultimately would have to be resolved in court. In
practice, when regulators initiate formal actions,
an insurer’s problems are sufficiently obvious that
the courts typically approve such actions. What we
cannot observe is regulators’ power to impose their will in informal actions that are not subject to public disclosure.

Insurer receiverships involving liquidation can be long and protracted affairs that are largely controlled by the domiciliary regulator. An in-house or outside receiver is appointed to manage all aspects of the receivership, including the disposition of claims and the marshalling and selling of assets. Further, receiverships are typically administered through state rather than federal courts. Historically, receiverships have tended to be very opaque to outsiders, and very little information is conveyed to various stakeholders and the public. Significant concerns have been raised that receivers sometimes unnecessarily prolong and milk their receiverships for their own financial gain. It is difficult to assess the severity of this problem because of the lack of public information and oversight, but research suggests that the receivership system increases insolvency costs (Grace, Klein, and Phillips 2002b).

An insurer’s liquidation can trigger the involvement of insurance guaranty associations (GAs). Each state has separate guaranty associations for property-casualty and life-health insurers. These associations cover a portion of the insolvent insurer’s unpaid claims obligations. Each state’s guaranty association covers the unpaid claims in that state regardless of where the insolvent insurer is domiciled. Only certain lines of insurance are covered, and there are limits on the amount of coverage for each claim. Insurance policies purchased by individuals and small businesses tend to have greater coverage than insurance purchased by large commercial buyers. Those with unpaid claims and other creditors stand in a long queue to seek recovery against the estate of an insolvent insurer and inevitably will receive only a portion of their claims, if anything.

All licensed insurers are required to belong to the GAs in the states in which they operate and to cover GA claims payments. Depending on state laws and the type of insurance, insurers may be able to recoup all or a portion of these assessments through rate surcharges and premium tax credits; these recoupment provisions vary by state and the type of insurer. Insurers also may deduct residual costs in calculating their federal income taxes. Baresse and Nelson (1994) estimated that the burden of GA assessments is distributed among different groups as follows: taxpayers, 54 percent; policyholders, 21 percent; and equity holders, 25 percent.

Guaranty associations have been criticized for creating moral hazard among insurance buyers and reducing market discipline (Cummins 1988; Lee, Mayers, and Smith 1997). It is difficult to determine how severe this problem is. Personal lines buyers may be unaware of GA coverage or simply may assume that the government will make them whole if their insurer goes bankrupt. Commercial insurance buyers, presumably, are savvier and understand their exposure. Arguably, market discipline should be stronger in commercial lines markets where GA coverage is limited or nonexistent and buyers are better positioned to assess the financial risk of insurers (Epermanis and Harrington 2006). Some have proposed that US GA assessments (or premiums) should be risk based to diminish the moral hazard problem. However, these proposals have been rejected by regulators who question their feasibility and likely benefits.

**Transparency and Market Regulation**

In the US, transparency is a mixed bag. Insurers’ financial statements and certain other reports are available to the public; however, any regulatory assessments of an insurer’s financial condition and risk are confidential, and there is no distribution of any internal analysis a company may have performed. At the same time, rating agencies play an important role in informing buyers, intermediaries, and other stakeholders about insurers’ “claims-
paying ability.” Rating agencies use reports filed with regulators and other information provided by insurers to grade their financial conditions. They also employ qualitative methods to a greater degree than regulators. The agencies’ ratings and analysis are made available to the public in a form that is easier to interpret than insurers’ financial statements. Hence, they are critical facilitators of market discipline. However, a significant number of insurers are not rated by a major rating agency (for example, A.M. Best only provides letter grade ratings for two-thirds of the companies listed in its Best’s Key Rating Guide).

Regulating insurance markets (such as prices, products, and trade practices) is fairly extensive in the US. Regulating an insurer’s market practices is principally delegated to each state in which it operates. Hence, each state effectively regulates its insurance markets. The scope of market regulation is broad (potentially encompassing all aspects of an insurer’s interactions with consumers), and the states’ policies vary significantly. State regulation of insurers’ prices or rates is a particularly visible and controversial topic. The rates for personal auto insurance, homeowners insurance, and workers’ compensation insurance are subject to some level of regulation in all the states, but the degree to which regulators seek to constrain prices differs.25 The extent of price regulation for other commercial property-casualty lines tends to vary inversely with the size of the buyer; markets populated by large buyers are subject to less regulation. The rates for certain types of health insurance may be regulated, but the prices of life insurance, annuities, and related products are only indirectly regulated through the product approval process.

Insurers’ policy forms and products also are closely regulated, with the exception of products purchased by large firms. Regulators must pre-approve most policy forms (except those for large buyers) before they are offered in the market. Other aspects of insurers’ market activities—such as marketing, underwriting, and claims adjustment—generally fall within the area of “market conduct” regulation. A state may impose some specific rules regarding certain practices, such as constraining an insurer’s use of certain factors in underwriting or mandating that they offer coverage to all applicants.26 Beyond this, regulation tends to be aimed at enforcing fair practices based on regulators’ interpretation of what this means.27 Further, intermediaries must obtain a license in every state in which they sell insurance and are subject to certain regulations regarding their conduct and continuing education requirements.

The scope, nature, and variety of market regulations raise questions about their necessity, efficiency, costs, and benefits. Most experts agree that some level of market conduct regulation is warranted, such as rules and sanctions against abusive marketing practices. Beyond that, there is considerable disagreement about other market regulations. Insurers and economists generally agree that price regulation is unnecessary (and potentially harmful) given the highly competitive nature of insurance markets, but many regulators have a different view. Excessive constraints on insurance products, including mandated benefits or coverages, raise costs and stifle choice as well as innovation. Intrusive interference with other aspects of insurers’ activities, especially underwriting and claims adjustment, create additional problems. Some of these policies may arise from regulators’ and legislators’ sincere belief they are necessary to protect consumers. Others are likely politically motivated to appeal to consumers or other interest groups.

There have been some efforts to lessen and streamline market regulation. For example, many states have deregulated commercial lines insurance rates and products that buyers, as well as insurers, have advocated. More states, in recent years, have moved to competitive rating systems for personal lines insurance. Further, the NAIC has
established centralized filing systems for property-casualty rates and policy forms, and life insurance policy forms. While these steps have been helpful, many insurers believe they are inadequate. Each state still retains its authority to impose its specific rules as well as approve the rates and policy forms that insurers are required to file.\textsuperscript{28} This reality has motivated many insurers to advocate some form of federal regulation.\textsuperscript{29} Even insurers that do not support federal regulation advocate deregulation of insurance prices and other aspects of their market activities.

**Empirical Evidence on the Effectiveness of Regulation and Market Discipline**

Empirical research and evidence on the effectiveness of insurance regulation fall into several categories. A handful of studies have looked at the effect of regulation on insolvency costs. Many more studies have tested the ability of RBC and/or regulatory early warning systems to predict insolvencies, separately or in conjunction with other predictors. And extensive research has considered the effects of price regulation in personal auto insurance and workers’ compensation insurance. A full literature review is beyond the scope of this paper, but we can briefly summarize research findings and other empirical evidence.

Studies have found that the relative cost of insolvencies is much higher for insurance companies than for banks. Grace, Klein, and Phillips (2002b) estimated the average cost of property-casualty insurer insolvencies (over the period 1986–1999) to be $1.10 per $1 of pre-insolvency assets.\textsuperscript{30} Non-regulatory factors probably account for some of the disparity; the operative question is whether regulatory policies also contribute to higher insurer insolvency costs. Willenborg (2000) and others point to the problem that regulators’ ability to tap guaranty associations to cover insolvency costs could induce excessive forbearance in their dealings with troubled insurance companies.\textsuperscript{31} Grace et al. (2002b) found evidence of three major factors contributing to higher insurer insolvency costs: (1) the financial condition of an insurer prior to insolvency and its managers’ moral hazard incentives; (2) regulatory forbearance; and (3) regulatory management of insurer receiverships. They suggest that improved financial monitoring and greater transparency surrounding domiciliary regulators’ intervention and receivership management could reduce insolvency costs.\textsuperscript{32} Some might also argue that measures that would facilitate greater market discipline would be beneficial and potentially would reduce the need for stricter regulatory standards, at least in certain markets (Harrington 2004; Epermanis and Harrington 2006).

This brings us to the question of the accuracy of RBC and regulatory financial monitoring systems. Numerous studies have tested various indicators or predictors of insurer insolvencies. Some of these studies have found that RBC ratios make a marginal contribution to insolvency prediction, at best. Although an insurer’s RBC ratio is not intended to be an insolvency predictor, this research raises questions about the accuracy and effectiveness of RBC standards.

Using logit analysis, Cummins, Harrington, and Klein (1995) tested alternative models that employed RBC in some form to predict insolvent (and solvent) property-casualty insurers and their tradeoffs with respect to Type 1 errors (failed insurers not predicted to fail) and Type 2 errors (surviving insurers predicted to fail). They found that less than one-half of the companies that became insolvent had TAC less than the company action level one to three years prior to its failure. They also found that a model that allowed the weights of the RBC components to vary and that included firm size and organizational form produced a material improvement in the Type 1/Type 2 error tradeoff relative to a model that used an insurer’s RBC ra-
ratio as the sole independent variable. Cummins et al. (1995) developed further empirical evidence of the deficiencies of the RBC formula.

The NAIC’s FAST scoring system has fared better than RBC in these studies, which is not surprising but is still important in assessing their relative contributions to solvency oversight. Grace, Harrington, and Klein (1998a) found that FAST scores are more accurate than RBC ratios in identifying property-casualty insurers that become insolvent. The FAST system had a success rate of between 40 and 91 percent in predicting property-casualty insolvencies, depending on the data sample used and the specified Type 1 error rate (ranging from 5–30 percent). In a second study, Grace, Harrington, and Klein (1998b) found that the FAST system was somewhat less accurate for life-health insurers, but its performance might be improved by adjusting the FAST scoring system based on empirical analysis.

These and other studies have found that financial monitoring could be further improved by incorporating more information and better methods, such as financial strength ratings and cash-flow testing (Cummins, Grace, and Phillips, 1999; Pottier and Sommer 2002). The cash-flow simulation used by Cummins et al. (1999) comes closest to the DFA approach we discuss; its significant explanatory power in insolvency prediction tests lends support to its consideration in determining capital adequacy and financial monitoring. It is difficult to estimate the effect of using more qualitative methods and information, as these things do not lend themselves as easily to empirical testing. The predictive value of claims-paying ability ratings comes closest to indicating the potential contribution of qualitative analysis, which is a part of the rating process.

The empirical case against insurance price regulation is strong. There is a long line of studies evaluating the effects of rate regulation in personal auto insurance dating back to the 1970s. The whole of the literature indicates that regulation does not benefit consumers by providing them with consistently lower premiums. However, the evidence also shows that regulators can cause significant market distortions if they seek to substantially constrain insurers’ rates. The negative effects of such policies include cutbacks in the supply of insurance, coverage availability problems, diminished quality of service, and higher claim costs.

For example, a recent study by Derrig and Tenyson (2008) found that Massachusetts’s strict rate controls for auto insurance increased claims costs by 44–50 percent and regulation-imposed cross-subsidies increased claims costs in towns that were “subsidy receivers.” Danzon and Harrington (2001) found similar effects in the regulation of workers’ compensation insurance rates. A study by Klein, Phillips, and Shiu (2002) also found that stricter price regulation induces insurers to hold less capital that would be subject to regulatory expropriation.

When these kinds of regulatory policies are taken to the extreme, they can create severe market problems. Several state auto insurance markets experienced severe problems before the resulting crises compelled regulatory reforms. Consequently, studies have shown that deregulating prices in such markets have greatly improved the supply of insurance and their overall efficiency.

Broader studies that consider the full scope of insurance regulation and its effects in the US are harder to come by. A number of studies have looked at the efficiency of US property-casualty insurers and life-health insurers, but most have not attempted to assess the effect of regulation on insurers’ efficiency. Ryan and Schellhorn (2000) found that efficiency levels in the life insurance industry did not change after RBC standards were implemented. This is not necessarily surprising, as the vast majority of insurers already met the new standards when they were implemented.

A more recent study by Pottier (2007) found
that life insurers’ efficiency decreases as the number of states in which they operate increases. This inefficiency arises from several sources, including compliance costs, delays in introducing new products, regulatory barriers to entering state markets, and other constraints that inhibit competition. It also reflects the combined effects of state regulatory policies and a state-based framework. Pottier also found that a significant number of life insurers are operating below the minimum efficient scale for the industry, consistent with the findings of prior studies. It appears that most of the higher costs associated with this inefficiency are passed on to consumers through higher premiums. Grace and Klein (2007) concluded that creating an optional federal charter for life insurers would increase the industry’s competitiveness and efficiency and facilitate greater consolidation that would enable more companies to achieve higher economies of scale.

Quantitative Regulations for Capital Requirements

The Third Generation Insurance Directive of 1994 did not directly address solvency issues. Instead, the directive recommended that the rules-based set of minimum capital requirements introduced in the 1970s be reviewed. The European Commission, the body responsible for proposing legislation in the EU, responded with a “framework for action” for financial services. According to this plan, EU solvency regulation should be harmonized and reformed in two steps, called Solvency I and Solvency II. Solvency I regulations went into effect for member nations by January 2004, slightly modifying the existing solvency margin requirements, and mostly focusing on coordination issues (EU Directive 2002/13/EC for non-life insurers; EU Directive 2002/83/EC for life insurers; see European Union 2002a, 2002b). A limitation of these requirements is that they are derived by volume numbers such as premiums or claims, rather than being based on the insurer’s specific risk situation, often leading to undesired incentives. For example, through underpricing, an insurer lowers its capital requirements because its premiums are lower even though its risk has grown, all else equal. Volume-based requirements are easy to apply, but as has been mentioned often in the literature (Farny 1997), they tend to be too crude and their theoretical foundation too weak to achieve good risk management.

Largely in response to these problems, the European Commission initiated Solvency II, with the primary goal of developing and implementing harmonized risk-based capital standards across the EU. The intent is to focus on an enterprise risk management approach toward capital standards, meaning that it will provide an integrated solvency framework that covers all relevant risk categories and the dependencies across them. Solvency II’s current schedule is as follows: in July 2007,
the European Commission published a framework directive (EC 2007a), which has been under discussion in the parliament and industry. The EU parliament approved this directive’s final draft in April 2009. The next step is for each member country to implement the EU rules into national law. Solvency II should then become the general norm for insurance regulation in the EU by 2012. Most parts of Solvency II are already in place, and although modifications are still possible, major changes seem very unlikely. The implementation of Solvency II is well organized and on schedule, but as the political process is not predictable, there still might be a number of obstacles that the EU regulators have to overcome before Solvency II will be the new standard. However, compared to the situation in the US where a major reform currently seems far away, there is a broad consensus among the EU countries that it is time for a broad reorganization of the solvency standards. This consensus is shared not only by regulators but also by politicians and in the industry (Steffen 2008).

A number of institutions are involved in setting Solvency II standards. Most notable is CEIOPS, which is responsible for managing the entire process. Among other efforts, CEIOPS is undertaking comprehensive consultations with all market participants, in which suggestions for future solvency rules are collected and discussed. They are also undertaking quantitative impact studies, in which the proposed rules are tested and discussed. Our view is that the institutions are providing mechanisms for interested parties to participate in rule development, as well as mechanisms to anticipate the effects of the ultimate outcomes.

All indications are that the final Solvency II regulation will be very similar to the corresponding regulation in the banking industry, Basel II (Basel Committee on Banking Supervision 2001). Both are based on three pillars: (1) quantitative requirements, (2) qualitative requirements and supervision, and (3) supervisory reporting and public disclosure. Under the first pillar—the quantitative requirements—each insurer’s available capital is compared to standards. The first level is the minimum capital requirement (MCR), a minimum amount of equity capital that an insurer must hold. The second level is the solvency capital requirement (SCR), also called “target capital,” which is intended to represent the economic capital the insurance company needs to run its business within a given safety level. In the context of Solvency II, the economic capital is derived by value-at-risk at a 99.5 percent confidence level over a one-year time horizon. In determining the SCR, all relevant risk categories are covered, that is, insurance, market, credit, and operational risk. Furthermore, risk mitigation techniques applied by insurers (such as reinsurance and securitization) are taken into account. The MCR will be a fraction of the SCR, although the precise value is not yet determined. One option is for the MCR to equal one-third of the SCR, the so-called “compact approach.” A second option is for the MCR to be measured as value-at-risk, similar to the SCR, but calibrated at a 90 percent confidence level instead of 99.5. This second method is called the “modular approach” (CEIOPS 2006). A minimum floor for the MCR is also established at about €2 million for life insurers and €1 million for non-life and reinsures (European Commission 2007a, 118).

Regulators are considering several methods to calculate MCR and SCR. One is to use a standard model that is given by the regulator. Another is to use an internal model, which the insurer itself develops and which might be used for the target capital calculation after being approved by the regulator. Internal models offer a number of advantages, including that they are individualized and therefore can be made to fit the insurer’s specific needs, rather than a one-size-fits-all standard model. Another advantage is that internal models might trigger innovation in insurer risk manage-
ment practices. Furthermore, the option to use internal models provides the insurer an opportunity to integrate regulatory requirements into its risk management process. Regulatory and business objectives then go hand in hand and lead to more efficient regulation and risk management (Financial Services Authority 2007). For all these reasons, large insurers are likely to use internal models. Some small insurers, however, might not have sufficient personnel and financial resources to develop such internal models, leading them to prefer a standard model. Yet even standardized models allow for some use of personalized parameters while providing standardized simplifications for small and medium-size enterprises (European Commission 2007b, 9).

Both with standard models and internal models, assets and liabilities must be estimated at market values. Relying on market values should ensure a realistic picture of an insurer’s risk capacity, especially compared to a situation where balance sheet values are used for regulatory purposes. As can be seen in the left part of Figure 1, two values need to be estimated: the market value of the liabilities and the market value of the assets. The market value of the assets minus the market value of the liabilities gives the available solvency margin. Estimating these market values is not trivial, especially if no market prices are available. In this context, determining the market value of the assets is easier than estimating the market value of the liabilities. Calculating the market value of liabilities, referred to as the “technical provisions,” is based on their current exit value, that is, the amount necessary to transfer contractual rights and obligations today to another undertaking (Esson and Cooke 2007; Duverne and Le Douit 2007). The technical provisions are then given as the best estimate of the liabilities plus a cost-of-capital–based risk margin.

A market-consistent valuation of risk requires the implementation of sound financial methods that account for the relevant sources of uncertainty in the cash flows. Future cash flows must therefore be estimated and risk adjusted either by reducing the cash flow and discounting with a risk-free interest rate or by discounting with a risk-adjusted discount rate. Estimations of future cash flows are complicated by the number of options in the

Figure 1: Pillar I of Solvency II
Insurance contracts, often requiring the use of option pricing methods to incorporate these in the estimation process. Solvency II thus supports the use of modern financial tools in insurer risk management processes.

After estimating the market values of assets and liabilities, adequate estimators to describe the risk of loss or of adverse change in the value of assets and liabilities need to be found. Under the Solvency II SCR standard formula, individual risk modules cover different risk types, that is, one module estimates underwriting risk (with three sub-modules for life, non-life, and health), a second estimates market risk, and a third estimates counterparty default risk. These three risk modules are aggregated to the so-called basic solvency capital requirement (BSCR). A capital requirement for operational risk (OpRisk) and an adjustment for the loss-absorbing capacity (LAC) of technical provisions and deferred taxes are added to the BSCR, yielding the following SCR formula (European Commission 2007a, 105 and 323):

\[
\text{SRC} = \text{BSCR} + \text{OpRisk} + \text{LAC} = \sqrt{\sum \sum \text{Corr}_{ij} \cdot \text{SCR}_i \cdot \text{SCR}_j + \text{OpRisk} + \text{LAC}}
\]

The factor Corr_{ij} denotes different items in a correlation matrix given by the regulator (European Commission 2007a, 324). Underwriting risk, market risk, and counterparty default risk are thereby correlated among each other, but these three are independent of operational risk. All risk modules are further subdivided; for example, the underwriting risk modules for non-life and health are subdivided in two sub-modules (European Commission 2007a, 107):

- Premium and reserve risk: the risk of loss, or of adverse change in the value of insurance liabilities, resulting from fluctuations in the timing, frequency, and severity of insured events, and in the timing and amount of claim settlements.
- Catastrophe risk: the risk of loss, or of adverse change in the value of insurance liabilities, resulting from significant uncertainty of pricing and provisioning assumptions related to extreme or exceptional events.

For life insurers, sub-modules such as mortality, longevity, disability-morbidity, or lapse risk are considered. The market risk module contains sub-modules for interest rate risk, equity risk, property risk, spread risk, concentration risk, and currency risk. When appropriate, the SCR standard formula also allows the use of insurer-specific parameters and standardized simplifications for small and medium-sized insurers.

Depending on the relationship between the amount of available capital to the SCR and MCR, there are three levels of regulatory intervention. When the available capital is above the SCR, there is no intervention. If the available capital is below the SCR but above the MCR, the regulator will take action aimed at restoring the insurer to a healthy condition. If the available capital is below the MCR, the regulator will revoke the insurer’s license. This will be followed either by liquidating the insurer’s in-force business or by transferring the insurer’s assets and liabilities to another insurer (European Commission 2007b, 5).

Importantly, Solvency II follows a principle-based approach instead of using strict rules such as those required in the US risk-based capital standards. A major drawback of standard rules-based models is their lack of flexibility to handle individual situations, limiting the ability to assess the wide range of insurance risk profiles. Rule-based approaches also increase the possibility of a systemic problem arising from the entire industry responding to a condition in the same or similar way. Principles-based regulation should encourage greater levels of individuality. But these advantages
do not come without drawbacks. Relying upon principles increases the complexity and costs of regulation, both for the insurer, who needs time and resources to implement the principles into a model, and for the regulator, who needs sufficient resources to control all the individual models instead of one standard model. Furthermore, a lack of precise guidelines could create inconsistencies in the application of standards across organizations and thereby reduce comparability (see Toppe Shortridge and Myring 2004 for a related discussion in accounting). This problem is especially relevant if principles are not properly enforced (see Black et al. 2007 for more details on the pros and cons of principle-based regulation).

**Qualitative Elements of Supervision**

The developers of Solvency II recognize the need for qualitative assessment in addition to the quantitative capital requirements described in the last section (Conference of Insurance Supervisory Services of the Member States of the European Union 2002). This need is highlighted by results from a study of twenty-one insurer failures (and a larger set of near failures) in the EU, which demonstrated that the fundamental causes of insurer insolvencies are management error rather than undercapitalization (Ashby et al. 2003). Based on these findings, Ashby et al. (2003) recommend a number of regulatory responses to bolster internal controls, most of which involve on-site inspections, offering expert advice, and similar actions that respond to specific situations rather than imposing universal requirements.

Such qualitative requirements represent the second pillar of the Solvency II framework and thus one of the building blocks of the new regulatory framework. The underlying theory of the second pillar is that the risks recognized by quantitative models in the first pillar must be handled with appropriate processes and decisions in the context of a management system. Quantitative models alone are insufficient. The central instrument of the second pillar is the supervisory review process (European Commission 2007a, 7). This supervisory review comprises an evaluation of the strategies, processes, and reporting procedures established by the insurer as well as the risks the insurer faces or may face and its assessment ability. The regulator also reviews the adequacy of the insurer’s methods and practices to identify possible events or future changes in economic conditions that could have unfavorable effects on its overall financial standing.

An example of the requirements within the second pillar is that all insurers should have a regular practice of assessing their overall solvency needs with a view to their specific risk profile (referred to as the “own risk and solvency assessment”; see European Commission 2007a, 9). The supervisory authority reviews results of this internal assessment process as a part of the supervisory review process. The review process also includes outsourced activities. To do that, the supervisor must have a right to access all relevant data held by the outsourcing service provider as well as the right to conduct on-site inspections of the outsourced activity, even if the outsourcing service provider is an unregulated entity in a third country.

In order to make this supervisory process efficient, regulators again need to have sufficient resources, including a follow-up process to review their findings. Furthermore, effective regulation requires appropriate monitoring tools that enable deteriorating financial conditions to be identified and remedied. As a result of the supervisory review process, the regulator might require the insurer to hold more capital than the SCR determined under pillar one of Solvency II. The regulators can thereby compel an insurer to undertake remedial actions if the qualitative analysis reveals problems even if the insurer exceeds its SCR. This is especially relevant when the standardized formula does not entirely reflect an undertaking’s specific
Insurance Regulation in the U.S. and E.U.

The capital add-on must be reviewed at least once a year.

Although EU regulators are working diligently to prevent insolvencies, a fundamental principle of Solvency II is that regulators will not prevent insolvencies at any price. As shown, the capital requirement is based on a ruin probability of 0.5 percent. In reverse this means that the insurer will fail on average once in two hundred years (or one out of every two hundred insurers will fail this period). Of course, increasing these requirements to 0.1 percent would increase the insurer’s capital requirement and its costs. To assess the benefit of increasing capital requirements, these costs should be compared to the costs of a failure. The use of guaranty mechanisms must also be considered. Solvency II does not cover guaranty mechanisms, but they are generally available in the EU member countries. An example is the Protector and Medicator Fund in Germany (for life and health insurance contracts) and the Financial Services Compensation Scheme in the UK (which covers life and most general insurance policies, such as motor, home, and employers’ liability insurance; reinsurance, marine, aviation, transport business, and credit insurance is not covered). A good overview of the variation across EU guaranty mechanisms can be found in OECD (2002, 50–53). Existing guaranty schemes are not affected by the introduction of the Solvency II rules.

Market Entry, Rate Regulation, and Profit Distribution

Beyond solvency regulation, other classic fields of supervision include market-entry regulation, rate regulation, and profit regulation. Regulating market entry, premiums, and profits were very common in the EU until the 1994 deregulation. Today most of these regulations do not exist although differences continue among the EU member countries and across some regulated fields in the national markets.

With the 1994 introduction of the so-called “country-of-destination principle,” market entry regulation has been simplified significantly throughout the EU. Once an insurer receives a license from a regulator to sell insurance products, that license is valid for all other member countries. To obtain a license, insurers must fulfill certain requirements, such as holding the absolute minimum capital required (€2 million for life, €1 million for non-life and reinsures) and submitting a business plan covering the next three years. Life insurers are also required to hire an actuary responsible for calculating premiums and reserves in line with regulations.

Direct rate regulation was common in the EU until 1994, but was then eliminated with the introduction of the Third Generation Insurance Directive. Some member countries, however, still regulate other conditions that affect the determination of insurance premiums. An example is the automobile insurance bonus-malus system in France (Dionne 2001). While there are no regulations governing the pricing of a contract, the premiums are adjusted by a bonus-malus coefficient that takes into account the driver’s past experience. These bonus-malus coefficients are set by law. Even though they set barriers on insurers, these rules are completely known; insurers can anticipate them and therefore incorporate them into the pricing process, so the competition in French automobile insurance continues even if constrained.

Many country-specific differences in the EU emerge from the fact that the individual states still regulate contract law. EU legislators tried to harmonize contract law, but due in large part to the divergent histories and underlying theories of the legal systems in the EU member countries, insurance contract law has not yet been harmonized. A number of differences in contract terms, therefore, can be found in the EU countries. Examples are
the right of withdrawal, disclosure requirements, and documentation requirements that might differ among EU countries. In some lines of business the freedom of contract is restricted. An example is that in Germany, Denmark, and Italy, automobile third-party liability insurers are obliged to enter into a contract with the customer; that is, they are not allowed to refuse an applicant. Nor are insurers in these countries allowed to discriminate among customers in order to separate good risks from bad risks. Such an obligation to enter into a contract is not known in other EU automobile third-party liability insurance (Basedow and Fock 2003).

Another example is surplus participation, a kind of profit regulation that still exists in the German life insurance industry (Rees et al. 1999, 373). According to “surplus participation,” life insurers are obliged to share their annual profit between the policyholders and the shareholders in designated ways. At least 90 percent must be paid out to the policyholders, while shareholders can take no more than 10 percent. Contract terms are also strictly regulated in the German automobile insurance market, limiting competition to pricing differentials rather than to contractual distinctions. Yet even with these various regulatory constrictions, regulation in the EU insurance industry is not too extensive, especially compared to the situation before the deregulation in 1994.

Insurer receivership is another field not yet harmonized in the EU. Although the EU developed receivership rules in 2000, insurance undertakings and credit institutions were excluded from the regulation. Justification for excluding insurance and credit organizations was based on the extremely wide-ranging powers of intervention held by national supervisory authorities, as well as on the existence of special arrangements for insurance and credit institutions within country-specific legislation (Council Regulation [EC] no. 1346/2000, Article 9; see European Union 2000). Considering German law as an example, the receivership process is comparable to that in the US, especially in the dominant role of the domiciliary regulator. A major difference, however, is that the process runs through the court of bankruptcy rather than the insurance supervisor. The court nominates a representative who manages all aspects of the receivership in the case of an insurer’s failure (German Insurance Supervision Act, Article 78; see BaFin 2009). We are unaware of any research on the relative efficiency of the receivership system in the EU.

Empirical Evidence on the Effectiveness of Regulation and Market Discipline

While numerous studies test the US solvency model and consider other aspects of US supervision, very few studies employ European data to analyze supervision-related questions. One exception is the field of efficiency analysis (data envelopment analysis, stochastic frontier analysis; see Eling and Luhnen 2009) where a number of studies test the influence of regulation in the European insurance markets:

- Diacon et al. (2002) observed decreasing efficiency for the years 1996–1999 considering non-life insurers from fifteen different countries.
- Ennsfellner et al. (2004) established strong evidence that deregulation had positive effects on the production efficiency of Aus-
tarian insurance companies for the period of 1994–1999.

- Hussels and Ward (2006) did not identify clear evidence for a link between deregulation and efficiency, again for the UK and German insurance markets during the period 1991–2002.
- Fenn et al. (2008) observed decreasing costs and increasing returns to scale for a large number of EU insurance companies. They concluded that mergers and acquisitions, facilitated by the liberalized EU market, have led to efficiency gains.

The aim of the 1994 deregulation in the financial services sector was to improve market efficiency and enhance consumer choice through more competition. As can be seen from this discussion, the evidence on efficiency gains due to deregulation is quite mixed. The limited evidence for single countries and the limited number of years of data to study, however, indicates that much future research is needed to provide general evidence regarding European systems and/or experiences that would provide useful input in developing an appropriate European solvency regime. Thus there is need for further research.

Another aspect of efficiency that has been analyzed in academic literature is the efficiency of the French pricing system, including the previously discussed bonus-malus regulation. Dionne (2001) showed that the variables used under the bonus-malus system (such as age, sex, and driving experience) efficiently deal with adverse selection. Moreover, he demonstrated that the resulting bonus-malus variable is significant in explaining both the individual distribution of accidents and the individual choice of insurance coverage. He concludes that it represents a valuable source of information, one that should create appropriate incentives in this market. Similar results were obtained by Chiappori and Salanié (2000) and Dionne (2001).

One new and important aspect of insurance regulation under Solvency II is market transparency via disclosure requirements. The Solvency II rules require insurers to submit annually a report covering essential and concise information on their solvency and financial condition (European Commission 2007a, 10). Public disclosure constitutes the third pillar of the Solvency II framework. A transparent process with public disclosure requirements is expected to result in market participants forcing appropriate behavior. Market discipline is expected to encourage a strong and solvent insurance industry.

Today’s evidence of market discipline in the EU insurance markets is still limited. For example, El-ling and Schmit (2008) found some market discipline in the German insurance market, but their evidence is less clear than that for other insurance markets (see Epermanis and Harrington 2006 for an analysis of the US market) or other fields of the financial services industry (Sironi 2003; Distin-guin et al. 2006). The new disclosure requirement under Solvency II could be a valuable data source for market participants, perhaps increasing market discipline. The new data might also be useful to analyze the success of the new solvency rules in the coming years.

**Comparison of United States and European Union Insurance Regulation**

The prior detailed discussion on insurance regulation in the US and the EU illustrates the various ways in which the two regimes are similar
to and different from one another. Here we offer a brief outline of several general themes that emerge from that discussion. In doing so, we highlight both the differences between the US and EU as well as their relationship to economic principles of efficient regulation.

Insurance regulation has long been justified by its proponents based on what constitutes good public policy or serves the public interest. Because insurance aids economic development, the argument goes, its fair operation is crucial to society. Furthermore, a competitive market may be hampered by informational limitations. Within the domain of solvency regulation, many economists have argued that agency problems and costly information offer a general rationale for governmental intervention (Munch and Smallwood 1981). When a market is hampered by agency problems and costly information, it is believed subject to “risk-shifting moral hazard,” whereby equity holders have incentives to extract value from debt holders through excessive risk taking. In the insurance context, equity holders have an incentive to take more risk than is optimal for policyholders. Although risk-taking behavior may be mitigated by the existence of franchise value (Staking and Babbel 1995), the problem is particularly acute in insurance because of the long-term nature of many insurance contracts, which allows management to increase risk after entering into contractual arrangements with its policyholders. The regulatory role in this situation is to “limit the degree of insolvency risk in accordance with society’s preference for safety” (Klein 1995).

Regulators have performed this role historically by imposing minimum capital and various other financial requirements.

Until the 1990s, solvency regulation in both the US and the EU set fixed minimum capital standards. With the introduction of “risk-based capital” (RBC) in the US, a move began toward using individual insurer characteristics to determine its capital requirement. While the US moved in this direction earlier than the EU, and had a shorter distance to travel, the EU appears to have caught up and surpassed the US with its recent focus on principles-based solvency regulation. RBC standards in the US remain somewhat static and focused on accounting data. In contrast, the EU is developing models that utilize dynamic financial analysis and add flexibility in incorporating individual insurer characteristics.

As presented above, most studies of the US RBC system indicate that it is a relatively poor predictor of solvency. While the US RBC formula is not intended to be a solvency predictor, its relatively subpar performance in empirical testing raises questions about its accuracy in determining capital requirements. These results suggest that using dynamic financial analysis (DFA) and qualitative methods could improve current solvency regulatory tools in the US substantially. In this sense, then, the likely results of Solvency II, which incorporate those tools, will be to improve regulators’ ability to anticipate financial weaknesses and take action early. Solvency II also is expected to encourage insurers to manage their financial risk more prudently. What is less clear is whether or not the benefits of these new rules will outweigh the costs of additional complexity (Elting, Schmeiser, and Schmit 2007). This question arises when considering the rules that will determine whether insurers will be compelled to use an internal model versus a standard model that could apply to all insurers. The standard model could incorporate DFA.

Beyond capital requirements, the US imposes many additional financial requirements in numerous forms, including many rules governing insurers’ financial structure and transactions, expectations for an array of financial ratios, extensive reporting of financial results, regular financial audits, and participation in guaranty associations. These requirements are costly and sometimes
opaque. In both jurisdictions, we believe that market transparency through easily accessible information could be improved. In the US, rating agencies and the National Association of Insurance Commissioners (NAIC) offer extensive financial information regarding most insurers. Commercial policyholders are particularly aided by such information. Still, public information available on US insurers may not provide accurate indications of their financial risk. This same type of information has not been the standard throughout the EU, but it is being considered as part of the Solvency II requirements. Indeed, with the implementation of Solvency II, the quality of information available on European insurers could be superior to that available for US insurers. Given that the economic rationale for regulatory intervention rests on informational and agency problems, a focus on removing informational barriers and supporting market discipline would appear to serve solvency objectives.

In addition to solvency requirements, the US continues to impose a variety of strict pricing regulations in many state jurisdictions. The economic justification for price regulation is much more tenuous than that for solvency regulation. Competition precludes the need for regulation to prevent excessive prices. Further, effective solvency oversight and market discipline are better vehicles to address underpricing that would threaten an insurer’s solvency. Hence, there is no credible economic basis for insurance price regulation.

Prior to 1994, most pricing regulation in the EU focused on assuring prices sufficiently high to protect against insolvency. Since 1994, most price regulation has been abandoned in the EU. Today, regulation in the EU tends to allow competition to set prices. The initial change in philosophy was accompanied by numerous insolvencies in several jurisdictions, but it seems now to have settled into equilibrium (Cummins and Rubio-Misas 2006). A negative reaction such as this can be a common initial scenario when price floors are eliminated. Markets tend to stabilize as insurers adjust to a competitive environment. Again, an effective risk-based financial regulatory system combined with market discipline is likely to discourage chronic underpricing as well as other high-risk behaviors.

Numerous additional regulations associated with policy forms, advertising restrictions, licensing, and so on can be found across the US. Some are also found within the EU. In both systems, variations across jurisdictions are being considered. The Optional Federal Chartering concept in the US is receiving considerable attention and support, along with detractors. Within the EU, a desire to harmonize appears hampered primarily by larger issues, such as the more extensive question of contract law across borders. It may well be that within the EU, insurance regulations will harmonize more quickly than the general national contract laws.

Policy Implications and Future Research

What is the impetus for the striking difference between the static accounting system used in the US and the holistic management approach found under Solvency II? Answers to this question can be found in variations across the two markets and cultures, as well as in the timing of each system’s introduction. Creators of Solvency II are able to take advantage of research that has generated a broad consensus among academics, practitioners, and policymakers that neither the European regulatory rules from the 1970s nor the current regulatory framework in the US is meeting regulatory objectives most effectively. They also have the advantage of advanced computer systems that allow for development and use of more complex models. We perceive, therefore, that much can be
learned from the process being implemented under Solvency II.

The conceptual framework for and methods to accomplish risk management within financial institutions have evolved considerably in the past two decades. We see a movement toward enterprise risk management and the use of internal risk models with emphasis placed on dynamic financial analysis (DFA). An important facilitator of this development is the improvement in computing power that was not as readily available twenty years ago. Other facilitators are the increase in the speed of communication and the amount of data that can be transferred across business parties. Such technical progress is reflected in differences between the US and EU standards.

Yet, not only has technology seen massive changes in the last twenty years, but the competitive environment in the EU has undergone tremendous modification with extensive deregulation leading to increased competition (Eling and Parnitzke 2007). Improved market transparency and the entrance of foreign competitors led to intensive price competition, margin erosion, and cost pressure. There also were substantial changes in capital market conditions, such as the stock market crash from 2000 to 2003 and the historically low interest rates. Furthermore, the convergence in the financial services sector and developments in other fields of financial services, such as Basel II in banking, have influenced the new EU regulation.

The length of the process in the European Union, however, also provides a good example of how difficult it is to introduce a new, innovative system of regulation. The disadvantages of the old EU regulatory rules have been widely discussed and understood in academia and practice for many years (Farny 1997), yet thirty years passed between the old and new systems. Political decision making takes time, and in most cases a trigger is needed to push the development forward. In the EU this has been the formation of the common financial services market. The current financial market crisis that reveals the need for a regulatory reform might be such a trigger for the US.

Despite the ease with which we compare developments in the EU and the US insurance regulatory systems, we also acknowledge the environmental differences that must be considered in evaluating regulatory success. The US and EU insurance markets operate in distinct economies and cultures, both of which affect regulatory approaches. Any true evaluation of the potential influence of different regulations requires focus on the respective market, limiting our ability to draw direct and clear conclusions about the two regulatory approaches.

Nevertheless, we encourage US regulators to keep in mind a variety of ideas that emerge from the Solvency II process when revising the US system. One of these is the notion of a principles-based approach. While US regulators have indicated interest in exploring the broad application of a principles-based approach, there is no indication that they are poised to pursue a comprehensive set of reforms such as those being developed in the EU. A drawback of standard rules-based models as found in the US is that these have only very limited flexibility to handle individual situations. Therefore the US model might not be very effective in assessing the wide range of insurance risk profiles (Eling et al. 2008). In comparison, the principles-based approach found under Solvency II is flexible and captures individual risk profiles, such as by using the insurer’s parameters instead of those determined by the regulator. A principles-based approach could trigger innovation, as insurers are encouraged to develop and use their own risk models in order to determine the regulatory target capital. We anticipate competition among insurers to develop the best risk model in the market.
Another advantage in this context is that the principles-based approach allows the insurer to integrate regulatory requirements into its management process. Business and regulatory objectives then go hand in hand, which could lead to efficient regulation and risk management (Financial Services Authority 2007). Therefore Solvency II has the potential to improve management practices. Overall, Solvency II might create a superior atmosphere for innovation in EU insurance markets, which might also result in a competitive advantage for EU insurers compared to their US competitors.

These advantages, however, do not come without drawbacks. Relying upon principles could increase the complexity and costs of regulation both for the insurer, who needs time and money to implement the principles into a model, and for the regulator, who needs sufficient resources to evaluate all the individual models instead of one standard model. A major effort by regulators will be to assure that internal models are appropriate for the situation, and not methods to hide concerns specific to individual reasons. Such effort is costly in time and resources. For that reason we do not argue that there is a need for a centralized regulatory authority. Most academic experts believe that the efficiency of US regulation could be improved by creating a federal regulatory authority; however, the retention of a state-based system would not preclude more efficient and harmonized regulation. We should note that the idea of creating an EU-wide insurance authority with independent country (state) regulators has been discussed periodically and then abandoned. Of course, it is important to recognize that the US consists of states within one nation whereas the EU consists of sovereign countries within a unified framework. In either setting, what can be improved is the coordination between the different regulators; they therefore need to work on a mutual basis using the same principles, and they need a fast and efficient connection to transfer information.

We therefore argue for a flexible scheme, one in which risk-based capital standards are used as guidelines to assist insurers in managing their risk structures rather than as absolute requirements (Eling et al. 2007). Flexibility is likely to yield a variety of risk strategies, limiting the possibility of systemic risk inherent in using a single standard model for all or even most insurers. Model arbitrage would be less effective, too, given that the requirements are flexible rather than rigid. US regulators might also consider forming something akin to the Committee of European Insurance and Occupational Pension Supervisors (CEI-OPS), which has been given the task to redesign the EU regulatory framework and is conducting public forums in which suggestions for future solvency rules are being collected and discussed. In the US, the closest analog to a structure that would have any kind of real authority would be an interstate compact. An interstate compact has been used to “harmonize” the regulation of US life insurance products, and such a vehicle could be used to advance and harmonize other aspects of US insurance regulation.

Throughout this paper, we have presented specifics of a variety of insurance regulatory controls in the US and the EU. We further presented existing empirical evidence of the performance of some of those controls. Much additional research is warranted to assess the effects of recent and soon-to-be-implemented changes to those regulatory systems. Importantly, we encourage research on the effectiveness of various solvency models, the ability of market discipline to substitute for government intervention, and the ways in which insurance supervisors will be most effective in employing qualitative analyses of insurer practices. Implementation of Solvency II offers us a rich opportunity for a natural experiment on these open questions.
Notes

2. An insurance company must apply for a license in each jurisdiction in which it writes business. Only "surplus lines" or "non-admitted" insurers may sell insurance for certain designated lines or risks (determined by each state commissioner) without a license.

3. While large segments of the industry have been pushing for an OFC, it is strongly opposed by the states and other industry segments (for example, state and regional insurers, and local agents) that wield considerable political power. The US Department of the Treasury under the previous Bush administration supported an OFC and included it in its blueprint for revamping financial institutions' regulation (Treasury 2008). We expect that the Obama administration will issue its own plan for financial regulatory reform that will likely also address insurance regulation and may advocate an optional federal charter. This may add some impetus for an OFC, but it still faces strong opposition and it is uncertain where insurance will stand in the queue as the regulatory framework for all financial institutions is reconsidered and revamped.

4. Regulations governing insurers' investments provide a good example. Two NAIC model laws reflect different approaches, and the states have adopted one of these or developed their own specific rules.

5. The states' fixed minimum capital and surplus requirements range from $500,000 to $6 million, depending on the state and the lines that an insurer writes. The median fixed capital requirement is in the area of $2 million (Klein 2005).

7. An insurer's TAC is equal to its reported surplus with some minor modifications; for example, additional reserves required by regulators are added to an insurer's surplus in calculating its TAC.

8. The NAIC developed a model law to be adopted by the states that implements the RBC standards. All states have adopted the model law so the same rules have been established in each state.

9. In statistical language, this might be labeled as a “Type 1 Error.” Conversely, a situation where the RBC formula would not require a financially weak insurer to increase its capital to an adequate level would constitute a “Type 2 Error.” Klein and Wang (2007) demonstrate that only a small fraction of insurers fall below the company-

10. Based on the current formula, an insurer's RBC requirement increases proportionately with the amount of its premiums, assets, and loss reserves. However, arguably, according to the "law of large numbers," an insurer's risk does not increase proportionately with its size. With a size adjustment, a small insurer would have a higher relative RBC requirement than a large insurer, all other things equal.

11. For example, Feldblum (1996) suggests that better factors could be applied to the credit risk associated with reinsurance recoverables based on credit or claims-paying-ability ratings for reinsurers.

12. Regulatory activities in the US insurance system are not easily classified using the three-pillar framework. Many quantitative elements of US regulation are beyond capital standards that we discuss in this section. When it is discussed in an international context, the second pillar is more closely associated with qualitative aspects of the supervisory review, which includes an evaluation of an insurer's strategies, processes, and reporting procedures, the risks it is or may be exposed to, and its management of those risks. US regulators may consider some of these elements when evaluating an insurer's risk management, but their approach tends to be more quantitative and rules-based than the approach envisioned in Solvency II.

13. In the US, regulators require insurers to adhere to the NAIC's Statutory Accounting Principles (SAP), which differ somewhat from the US Generally Accepted Accounting Principles (GAAP). SAP accounting is intended to measure an insurer's liquidation value, while GAAP is intended to measure the value of a company as a going concern. Within the last decade, the NAIC has sought to standardize and document SAP through a series of more than a hundred issue papers that address various aspects of SAP rules.

14. These reports include insurers' RBC calculations, actuarial opinions of reserve adequacy, CPA-audited financial statements, and management opinions. Most but not all of these reports are available for public access.

15. State laws generally authorize regulators to review all books and records of a company at any time.

16. The terms “bench” or “desk” audit refer to an in-house review of an insurer's financial reports performed within the offices of the insurance regulator. This is contrasted with an on-site examination or audit of an insurer that is performed at the insurer's offices and involves a review of its books and records.
17. The NAIC’s analysis activities are focused on larger insurers that write business in a significant number of states. A list of FAST scoring system ratios is published in Klein (2005). However, the parameters used in developing an insurer’s score remain confidential. The FAST scoring system is subject to more frequent modifications than the IRIS ratios.

18. NAIC analysis is confined to “nationally significant” companies, which are defined as companies writing business in seventeen or more states and having gross premiums (direct plus assumed) written in excess of $50 million for life-health companies and $30 million for property-casualty insurers.

19. Examiners have been encouraged to go beyond simply verifying the accuracy of an insurer’s financial reports and perform additional analysis to assess an insurer’s financial risk. One exception to this is mandatory stress testing by life insurers to demonstrate the adequacy of their policy reserves.

20. Klein (1995) argues that this allows domiciliary states to impose negative externalities on non-domiciliary states. This problem motivates the multilayered monitoring and regulatory system described earlier.

21. The maximum limit for property-casualty claims is typically $300,000, but some states have higher limits up to $500,000. Many states have also enacted provisions that exclude guaranty-association coverage for claimants with a net worth exceeding a certain amount, for example, $50 million.

22. Workers’ compensation is an exception—all workers’ compensation claims are covered by GAs, and there is no limit on the amount of coverage for each claim. This policy is intended to protect the claims of injured workers.

23. In calibrating models to predict insolvencies, modelers have to balance the ratio of Type 1 errors to Type 2 errors. Models can be calibrated to predict more insolvencies (that is, reduce Type 1 errors), but this raises the number of Type 2 errors. Ultimately, a maximum acceptable level of Type 1 errors has to be established for any model that might be used for regulatory purposes. More accurate models should offer better Type 1/Type 2 error tradeoffs to choose from.

26. Proposed OFC legislation would explicitly preclude price regulation. However, the legislation is essentially silent on other aspects of market regulation. Any legislation that is enacted could contain more provisions on other elements of market regulation and/or this could be left to the discretion of federal regulatory officials. Either way, the scope
and nature of market regulation under an OFC is uncertain although its advocates are hoping for less restrictive policies.

About the Authors

MARTIN ELING is Research Fellow at The Independent Institute, professor in insurance, and director of the Institute of Insurance Science at the University of Ulm (Germany). He received his doctoral degree from the University of Münster (Germany) and his habilitation from the University of St. Gallen (Switzerland). In 2008 he was visiting professor at the University of Wisconsin-Madison (US). His research interests include risk management, asset liability management, and empirical aspects of finance and insurance. He has published articles in leading international journals such as the *Journal of Risk and Insurance*, the *Journal of Banking and Finance*, and *Insurance: Mathematics and Economics*.

ROBERT W. KLEIN is Research Fellow at The Independent Institute, Director of the Center for Risk Management and Insurance Research, and an Associate Professor of Risk Management and Insurance at Georgia State University in Atlanta. Dr. Klein is a leading expert on insurance regulation and markets with 30 years of experience as a regulator and academic researcher. He has published extensively on various topics in insurance and its regulation, and he also has testified frequently at legislative and regulatory hearings on significant issues affecting insurance consumers and the industry.

Prior to joining Georgia State University in September 1996, Dr. Klein was the director of research and chief economist for the National Association of Insurance Commissioners. He also has served as staff economist for the insurance department and state legislature in Michigan. He has a B.A., M.A., and Ph.D. in economics from Michigan State University. Dr. Klein is a Sloan Fellow at the Financial Institutions Center at the Wharton School of Business. He has served on the Board of Directors for the American Risk and Insurance Association and currently serves on the editorial boards for the *Journal of Insurance Regulation and Risk Management* and *Insurance Review*.

JOAN T. SCHMIT is Research Fellow at The Independent Institute and holds the American Family Insurance Chair in Risk Management and Insurance at the University of Wisconsin, Madison, where she has been on the faculty since 1988. Currently, she is the senior associate dean of the Wisconsin School of Business, following a period as chair of the Actuarial Science, Risk Management and Insurance Department in the School of Business, one of the oldest such programs in the nation. She also serves as an affiliate faculty member at the University of St. Gallen in Switzerland.

Dr. Schmit has published extensively in insurance and legal journals. Her area of expertise is the interaction of law and economics, primarily focused on the effects of tort law. Recently, she has expanded her research into the enterprise risk management field, including projects sponsored by the Casualty Actuarial Society and Society of Actuaries, as well as a variety of other papers on the topic. Professor Schmit has enjoyed being an academic moderator for the International Insurance Society since 1997.
The Independent Institute is a non-profit, non-partisan, scholarly research and educational organization that sponsors comprehensive studies of the political economy of critical social and economic issues.

The Center on Entrepreneurial Innovation pursues research into entrepreneurship, the dynamic process of markets and technological innovation without regard to prevailing popular or political biases and trends. The goal is to explore important areas that might otherwise be ignored, including questions normally considered "out-of-the-box" or controversial, but which might well be crucial to understanding and getting at real answers and lasting solutions. As a result, the Center aims to cut through the intellectual poverty, noise, and spin of special-interest-driven public policy in the US and elsewhere.

THE INDEPENDENT INSTITUTE is a non-profit, non-partisan, scholarly research and educational organization that sponsors comprehensive studies of the political economy of critical social and economic issues.

The politicization of decision-making in society has too often confined public debate to the narrow reconsideration of existing policies. Given the prevailing influence of partisan interests, little social innovation has occurred. In order to understand the nature of and possible solutions to major public issues, the Independent Institute adheres to the highest standards of independent inquiry, regardless of political or social biases and conventions. The resulting studies are widely distributed as books and other publications, and are publicly debated in numerous conference and media programs. Through this uncommon depth and clarity, the Independent Institute expands the frontiers of our knowledge, redefines the debate over public issues, and fosters new and effective directions for government reform.

The Discriminating (Pricing) Actuary

Edward W. (Jed) Frees  
University of Wisconsin - Madison, Australian National University

Fei Huang  
University of New South Wales

Date of this Draft: March 16, 2021

Abstract: The insurance industry is built on risk classification, grouping insureds into homogeneous classes. Through actions such as underwriting, pricing and so forth, it differentiates, or discriminates, among insureds. Actuaries have responsibility for pricing insurance risk transfers and are intimately involved in other aspects of company actions and so have a keen interest in whether or not discrimination is appropriate from both company and societal viewpoints. This paper reviews social and economic principles that can be used to assess the appropriateness of insurance discrimination. Discrimination issues vary by the line of insurance business and by the country and legal jurisdiction. This paper examines social and economic principles from the vantage of a specific line of business and jurisdiction; these vantage points provide insights into principles. To sharpen understanding of the social and economic principles, this paper also describes discrimination considerations for prohibitions based on diagnosis of COVID-19, the pandemic that swept the globe in 2020.

Insurance discrimination issues have been an important topic for the insurance industry for decades and are evolving in part due to insurers’ extensive use of Big Data, that is, the increasing capacity and computational abilities of computers, availability of new and innovative sources of data, and advanced algorithms that can detect patterns in insurance activities that were previously unknown. On the one hand, the fundamental issues of insurance discrimination have not changed with Big Data; one can think of credit-based insurance scoring and price optimization as simply forerunners of this movement. On the other hand, issues regarding privacy and use of algorithmic proxies take on increased importance as insurers’ extensive use of data and computational abilities evolve.

Keywords: Actuarial fairness; disparate impact; proxy discrimination; unisex classification; credit-based insurance scores; price optimization; genetic testing; big data; COVID-19

1 Introduction

Discrimination is a topic that touches on the daily lives of almost every person. The word “discrimination” generally has negative connotations; people think of discrimination as occurring when we go into a store and are treated differently because of our hair color, when we apply for a job that we are well qualified except for our age, when we are shunned from a social group because of our ethnicity, heritage, or religious background. From this perspective, discrimination is endemic in our society and a topic that well deserves serious consideration.
This article focuses on discrimination in an insurance context. Insurance is particularly interesting because the entire industry is based on discrimination. Here, we use the word “discrimination” in an entirely neutral way, taking it to mean the act of treating different groups differently – where the groups are distinguished by salient features such as hair color, age, gender, heritage, religion, and so forth – whether such discrimination is justifiable or not. For example, auto insurers often charge younger (presumably riskier) drivers more than older (presumably safer) drivers, but do not make a distinction between brown-haired and red-haired drivers (presumably because the two groups are equally risky). So, discrimination based on age is done routinely, whereas discrimination based on hair color is not. In subsequent sections, we present different arguments about whether insurance discrimination is ethical or is “unfair” and morally indefensible in some sense.

1.1 How Insurers Discriminate

Insurers collect information on current and potential customers. They collect information about the customers themselves, the entity being insured (whether a person, organization, or physical object such an auto or home), where the entity is located (that can vary, such as a person or auto), and parameters about the contract desired, among other things. This information, represented as variables or factors, provide the basis that insurers use to form groups and make decisions. And by treating groups differently, they discriminate among them. Before describing the process of forming these groups and weighing in on whether or not the use of a specific variable is ethical, we first describe the set of actions that an insurer might take. In short, how do insurers discriminate among customers?

**Issuance, renewal, or cancellation.** The first stage is the decision to insure. We follow the structure of Avraham (2018) who notes that the harshest form of discrimination is the decision on whether or not to issue a policy because of some characteristic, such as the applicant’s religion or ethnicity. This may be at the underwriting stage or even earlier, at the marketing stage. For example, Section 2.3 describes classical issues of so-called *redlining* where insurers simply did not enter geographic districts with high concentrations of African-Americans (who were assumed to be high risks). A similar type of discrimination happens when insurers refuse to renew or when they cancel policies based on some characteristic. Indeed, some jurisdictions have statutes that limit or prohibit the use of a particular characteristic in either issuance, renewal, or cancellation of an insurance contract.

**Coverage.** Another form of discrimination involves restricting coverage in ways that might harm disadvantaged groups. For example, insurance companies might limit disability insurance coverage for people with disabilities that stem from having a human immunodeficiency virus (HIV).
**Pricing.** Even without limitations on issuance and coverage, insurance companies can still distinguish among insureds by simply charging different premiums. For example, an insurer may admit people with various diseases and disabilities into their pool, yet charge these people a higher premium. Is this fair or unfair? Some argue that a specific disease, e.g., cancer, is no fault of the individual and so they should not bear the additional burden of higher premiums. A counter position is that, by admitting high-cost individuals to the pool, this raises the costs for all in the insurer’s pool (even those without the specific disease).

1.2 **Insurance Prohibitions**

The modern-day insurance industry is founded on the ability to differentiate, or discriminate, among risks, known as *risk classification*. Thinking of an insurer as a private company, there are strong economic arguments for permitting insurers to discriminate among risks; Section 3 presents economic reasoning for this permission. There is evidence, consistent across lines of business and international jurisdictions, that insurance policyholders believe that some insurance discrimination is fair, c.f., Schmeiser, Störmer, and Wagner (2014). However, there are also instances where consumers are concerned with “unfair” discrimination. When insurance is mandatory or nearly so, it becomes less of an economic commodity and more of a social good, resulting in different attitudes towards “fairness.” Section 2 describes social justice considerations that underpin notions of fairness. Because of these concerns, regulators and policymakers in many jurisdictions impose restrictions on insurers abilities to discriminate.

Disagreements among stakeholders about what constitutes fairness can arise depending on whether one views insurance as an economic commodity or as a social good. Employees of insurers often think of insurance as an economic quantity and argue that risk classification is morally appropriate, c.f., concepts of *actuarial fairness* in Section 2. Consumer advocates focus on concepts of solidarity and cross-subsidization of risks, thinking of insurance as a social good, or a basic human right. These views depend markedly upon the jurisdiction and line of insurance business, as discussed in Sections 4.2 and 5, respectively.

Insurance discrimination, including the prohibitions from regulators that insurers might face and how these prohibitions affect society, has long been an important topic. Issues of fairness have not been resolved nor are they becoming less relevant; its prominence has lately increased with the increasing importance of “Big Data” where massive data sets and increasing computing power has become commonplace, c.f., Thouvenin et al. (2019). Like other major industries, insurers have at their disposal increasing amounts of information available about current and potential customers. As emphasized in Sections 5.5 and 6.4, more information gives insurers opportunities to differentiate among potential clients at
increasingly granular levels; many are doing so because of real or perceived pressures from competition. However, not all information that could be used should be used - we seek to provide a framework for actuaries and other analysts to think about the use of potentially sensitive information.

2 Social Justice Considerations

2.1 What is Actuarial Fairness?

To understand what is unfair discrimination and what insurers should be prohibited from doing, let us start with a discussion of “fair” insurance mechanisms. We begin with a historical context, drawing on the work of Frezal and Barry (2019).

2.1.1 Pooling and Solidarity

In the early seventeenth century, mathematicians used games of chance such as rolling dice and drawing lotteries to develop a theory of randomness. For example, the fair price for each participant in a lottery was determined by the sum of wagers divided by the number of participants. Fairness was thus understood within the framework of individual equitable contracts, ones that traded a certain present amount for an uncertain future value. Even though the ex-post results of the game had winners and losers, because the ex-ante probabilities were equal, such games could be accepted as fair.

Much later, in the nineteenth century, a similar mathematical model was used for insurance pricing. From an individual’s perspective, one could again trade a certain present amount, the premium, for an uncertain future value that would provide compensation for an insured loss. For an insurance pool, the sum of future values was no longer certain (unlike the lottery size) but, with the additional regularity in the sum of future value of losses, there were real benefits in pooling of risks. In the modern language of probability, although the amount that an individual might expect to lose for an insured loss remained unchanged, the amount of uncertainty was vastly reduced.

Insurance pooling offered a novel method for coping with the uncertainty of losses. Before this, the only method of coping with potential loss events was individual prudence. With an insurance pool, losses now became the responsibility of the pool. From a moral perspective, the responsibility for the accident could now be thought of as not due to the behavior of the faulty individual but rather attributed to the collective; in this sense, pooling socializes responsibility, c.f., Baker (2002).

As further discussed in Lehtonen and Liukko (2011), pooling creates a sense of shared responsibility among a group of people. This, combined with a certain understanding of
equality and justice, creates a type of insurance solidarity. It is not the same type of solidarity that one thinks of in political movements which embody a conscious identification with the group, emotional bonds, shared values and beliefs, and so forth. It is solidarity that emphasizes mutual responsibility, reciprocity, and a particular shared understanding of fairness. Insurance provides a mechanism to transfer an individual’s uncertainty to a pool; to achieve this agreement, the individual must have faith in the pool.

2.1.2 Responsibility and Actuarial Fairness

With the shift of responsibility from the individual to the pool, one can imagine that the sense of fairness shifts and depends upon the nature of the pool. If the pool is formed from a small group of like-minded individuals (think of the classical case of a group of farmers forming a collective to restore a member’s barn in the event of fire), then there will be little difference between notions of fairness for the individual and for the pool collective. However, modern day insurance is generally sponsored at large levels, either by governments or private corporations, the latter of which can be owned by policyholders (mutual or takaful companies) or by investors (stock companies). Members of the pool may feel a type of (insurance) solidarity but the responsibilities of the pool depend on its nature.

Stock Insurance Company. At one end of the spectrum is the case of the pool of contracts issued to individuals by a for-profit stock company. Here, the pool can be thought of as a sum of bilateral contracts that leaves out the collective dimension of insurance. Actuarially fair pricing is based on the expected value of the uncertain event at stake, taken to be the risk transferred from the insured to the insurer. In this context, fairness means that each customer should pay for their own risk and only their own risk. As will be discussed in Section 3, there is ample basis for this position from economic theory.

Government. At the other end of the spectrum is the case when the pool is owned by a government entity where such contracts constitute social insurance. Subsidies, from one group to another, are common in social insurance. Governments regularly engage in social policy such as the redistribution of risk or income. The use of insurance to subsidize the underprivileged is consistent with what many view as a government’s core mission. In social insurance, there can be a large variation in how strictly the principle of actuarial fairness is followed.

Group Insurance. Between these two ends of the spectrum, there is substantial variation in principles of fairness depending on who owns the pool and the nature of the contractual arrangement. For example, consider a disability income contract issued to a large group, such as a university. Because the employer (university) pays all or a major portion, premiums rated by risk factors are not a major issue (unlike the individual market). In
general, in group insurance, the amount of socialization is greater than one would find in the corresponding individual market.

As described in Baker (2002), most people do not think that their premiums will go to pay other people’s claims. Instead, they think of it as a type of savings account and often expect that over the course of a lifetime the deposits made by each person should roughly equal the withdrawals on that person’s insurance account. Thinking of premiums as going to pay others claims emphasizes the social aspect of insurance. That is, the losses, understood as belonging to the collective, are also borne collectively (Lehtonen and Liukko (2011), p. 35).

**Mutual Company.** In a mutual insurance company, the policyholders are both customers and owners. Unlike stock companies, ownership rights of the mutual policyholders are not transferable. By eliminating stockholders with their separate and sometimes conflicting interests, potential conflicts between owners and customers over dividend, financing, and investment policies are internalized. This is the major benefit of the mutual form of organization. As the owners of the pool are the policyholder themselves, this suggests that the amounts of cross-subsidies among groups or socialization would be greater than in an organization with a for-profit motive. However, in point of practice, mutuals compete with stock companies and so many of their practices are indistinguishable from stock companies. A small academic literature examines differences between stocks and mutuals, c.f., Braun, Schmeiser, and Rymaszewski (2015). In part due to the policyholder’s owner stake in the company, evidence from this literature suggests that policies offered by stock insurers are overpriced relative to policies of mutuals. Nonetheless, we know of no study that has confirmed nor disproved the conjecture that mutuals discriminate differently than stock insurers.

**Takaful.** As another example, consider modern takaful companies, c.f., Maysami and Kwon (1999). In many senses there are similarities between takaful and mutual companies. Classical Western insurance appears to violate the Islamic prohibition of gambling (as well as the Islamic prohibition of usury). Instead takaful insurance offers, not as a bilateral contract, a transfer of a known risk to a collective enterprise by which Muslims pool resources to aid one other in the event of loss. Responsibility of the loss shifts from the individual to the collective and so aspects of fairness shift.

### 2.1.3 Insurance as a Social Good

Attitudes towards fairness also depend upon whether an insurance product can be viewed as a social or type of public good. A social good is something that benefits the general public such as clean air, clean water, and literacy. One characteristic of a public good is that is *non-excludable*, that is, it cannot be provided unless others can also enjoy it. For example,
if you erect a dam to stop flooding - you protect everyone in the area (whether or not they contributed to erecting the dam). Thus, viewing an insurance product as public good would argue against excluding members of society.

For example, in many countries health insurance is likely to be seen as a social good where access to a certain level of healthcare is guaranteed for all. This is even true in a country like the U.S. which generally has taken longer to improve access to healthcare than other countries. In contrast, life insurance is more often seen as a private (non-public) economic commodity. Life insurance can enhance the financial security of the family of a policyholder but is voluntary and is not viewed as a necessity. Other insurance lines, such as long-term care and disability insurance arguably fall somewhere in the spectrum between social and economic private goods, c.f., Prince (2019).

If an insurance product is thought to be a social good, a related question is whether members of the public have equal access to the product. Specifically, the issue is whether there is an impact which puts members of a select “protected” group at a disproportionate disadvantage compared with members of a similar group. Issues of such disparate impact are difficult for individual insurers to address but are important for public acceptance of the insurance marketplace, c.f., Miller (2009). Regulators have been grappling with the question of whether laws, which prohibit discrimination based on race, religion, or national origin, could or should cover instances of disparate impact on underserved or protected classes of consumers emanating from the use of predictive modeling and analytics.

2.2 Characteristics of Sensitive Variables

Grouping, or classifying, insureds into homogeneous categories for the purposes of risk sharing is at the heart of the insurance function. Many variables that insurers use are seemingly innocuous (e.g., blindness for auto insurance) yet others can be viewed as “wrong” (e.g., religious affiliation), “unfair” (e.g., onset of cancer for health insurance), “sensitive” (e.g., marital status), or “mysterious” (e.g., AI produced). When regulators and policymakers decide that it is not permitted to use a variable for classification, it is thought of as creating a protected class. By and large, the choice of whether a variable should be used for insurance purposes is a normative one. Although actuaries and other financial analysts determine insurance premiums from the available information, the choice of which variables to use is a societal one in which many actors participate.

Nonetheless, it is helpful to understand what variable attributes influence society’s assessment of whether it is fair for insurance purposes. When identifying whether or not a variable contains sensitive information, we use a structure drawn from Avraham (2018) and Prince and Schwarcz (2020).
• **Control.** If an insured has control over an attribute, it is generally deemed to be an acceptable variable to be used for insurance purposes. For an example from auto insurance, consider a variable that indicates whether the car is high performance, capable of going at fast speeds and expensive to replace in the event of an accident. An insured chooses whether or not to purchase a high performance vehicle and so vehicle type is generally deemed to be an acceptable variable. In contrast, race and sex at birth are examples of characteristics over which insureds have no control. Naturally, questions of degree of choice enter; for example, smoking in life insurance is generally now accepted as a rating factor whereas religious affiliation is generally prohibited.

• **Mutability.** Does the variable change over time (such as age) or stay fixed? It is possible that rating by age is tolerable because we all get the same chance to be on the winning side and the losing side of it over the course of a lifetime.

• **Statistical Discrimination.** A variable should have some predictive value of an underlying risk. If it does not, then it is generally viewed as unacceptable for insurance purposes. As a rule of thumb, the better predictor of risk the characteristic is, the more tolerable such discrimination becomes. However, some pricing variables may not have such predictive abilities; Section 3.3 will sharpen this precept by distinguishing between “risk-based” and “non-risk” price discrimination in insurance.

• **Causality.** It is generally acceptable to use a variable if it is known to cause an insured event. For example, an individual diagnosed with cancer will generally be unable to purchase life insurance. Naturally, establishing causality is a much higher bar than mere correlation, or predictive ability, for a risk. For example, decades were spent building scientific evidence before it was widely established that smoking causes premature deaths, c.f., Peto (1994).

• **Limiting or Reversing the Effects of Past Prejudice.** Does an insurer’s use of a trait perpetuate negative stereotypes or otherwise subordinate disadvantaged groups? The historical use of the characteristic as a method of discrimination is also relevant; that is, whether the characteristic defines a socially salient group that has been disadvantaged in the past. In that sense, discriminating based on skin color is more problematic than based on eye color.

• **Inhibiting Socially Valuable Behavior.** Does an insurer’s use of a trait inhibit or prevent socially desirable activities? Section 5.1 describes how individuals, fearful of being denied life insurance, avoid participating in genetic testing research. As another example, Prince and Schwarcz (2020) cite U.S. laws that prohibit insurers from
discriminating on the basis of intimate partner violence because such reporting could
dissuade victims of violence from seeking needed medical care or police intervention.

Whether a characteristic is socially suspect or sensitive is context-dependent, depending
on the jurisdiction and the line of insurance business, as described in Sections 4.2 and 5.

2.3 Indirect Discrimination

One of the difficult questions in insurance discrimination is the treatment of related variables;
use of variables related to a prohibited variable constitutes indirect discrimination. These
are variables that, although they do not have the usual characteristics of an unfair variable
(Section 2.2), have undesirable effects on society. A classic example is redlining, a term that
refers to the practice of drawing red lines on a map to indicate areas that insurers will not
serve, areas typically containing high proportions of minorities.

Specifically, we can define indirect (insurance) discrimination as consisting of three ele-
ments: proxy discrimination, disparate impact, and whether or not the discrimination could
be avoided by other means. We address each in turn.

Proxy discrimination, also known as indirect statistical discrimination, occurs when insur-
ers discriminate based on a facially-neutral characteristic, such as the size of the car engine,
that correlates with a protected class, such as gender (in many studies, men like to drive
cars with big engines). In the case of redlining, insurers discriminate based on geographic
area (such as an urban area) that is correlated with race. Specifically, by avoiding certain
urban areas, they also avoid large groups of potential minority customers; this amounts to
at least partially making insurance decisions based on a protected variable.

It will be helpful to think about two types of proxies: one where an identifiable surrogate
such as geographic area serves as a substitute for a protected variable such as race, and one
where the proxy is produced by an algorithm that summarizes the effects of many variables.
Section 5.5 on big data emphasizes the increasing importance of the second type of proxy
discrimination as insurers utilize increasingly sophisticated algorithms and growing sources
of data. Empirical aspects of proxy discrimination are discussed further in Section 6.

The second element is disparate impact, i.e., whether there is an impact which puts mem-
ers of a protected group at a disproportionate disadvantage compared with members of a
similar group. Returning to the redlining example, this practice puts minority neighborhoods
companies is a more risky place for banks to lend. Without good financing opportunities,
fewer people invest in the neighborhood, and without investment the neighborhood becomes
an even more risky place for banks, causing further decline.”
These notions of proxy discrimination and disparate impact are drawn from the legal literature where it can be sometimes difficult to infer a precise mathematical formulation. For our purposes, we think of proxy association as the relationship between a protected variable and a set of one or more surrogate variables whereas disparate impact occurs when there is a relationship between a protected variable and an outcome of interest (e.g., insurance purchase). In Section 6.4, we supplement these definitions by drawing from the machine learning literature.

The third element is whether the criterion is motivated by a *legitimate business necessity*. If it is, then discrimination may be legal even in the event of producing a disparate impact. For example, Section 5.3 will describe models that optimize insurer’s profitably objectives, a legitimate business motivation, at the expense of disfavoring customers with fewer market options who tend to be low-income and minority consumers.

As another example, the Council of the EU adopted Directive 2004/113/EC Guidelines on the Application of the Gender Directive, “the use of risk factors which might be correlated with gender […], as long as they are true risk factors in their own right” is still permitted.

### 3 Economic Considerations

One approach to pricing is to think of an insurance contract as a type of financial investment. From this viewpoint, financial investors base risk transfers considerations on a *law of one price* that is dictated by forces of supply and demand in a competitive market. An advantage of this approach is that many issues of insurance discrimination become moot as prices are given by an external marketplace. Many readers will enjoy thinking about pricing of insurance contracts in the context of financial economics asset pricing theory, summarized by Bauer, Phillips, and Zanjani (2013).

However, even in personal lines (where there is much more homogeneity than in commercial lines), there is substantial heterogeneity among insurance products when considering the variety of contract features (deductibles, limits, coinsurance, and so forth), risk factors of the entity insured (e.g., auto or home), and risk factors of the insured (e.g., attitude toward risk) that exist. Because of this heterogeneity, insurance pricing is focused on the underlying *cost of producing the good or service*.

Like any firm, the price that an insurer charges is determined by the quantity where marginal cost equals marginal revenue. However, unlike other industries, determining marginal costs is difficult in insurance. In part this is because the production cost is random. By definition, insurance contracts are based on contingent events whose financial outcomes are uncertain. Further, even when an insured event does occur, the actual cost of an insured
claim may not be known for a long period of time.

As further developed in Section 4.1, insurance prices are based on the expectation of losses, a concept coined as an actuarially fair price in Arrow (1963). In a simple model, an actuarially fair price is the result of an assumption of zero profits and ensures that the insured will buy full insurance coverage. It is the foundation of insurance pricing.

### 3.1 Adverse Selection, Moral Hazard, and Incentives

Simple models can provide insights but are naturally limited in addressing the numerous features of real contracts. One feature particularly relevant to potential insurance discrimination is unequal access to information, known as information asymmetry.

Insurers traditionally face adverse selection, a problem that can arise when consumers know more about their own risk characteristics than insurers. Insurers argue that by knowing about risk factors, the entire marketplace is better. Indeed, the entire purpose of risk classification is to mitigate the problem of adverse selection. Extending this line of thought, the more information that insurers have about policyholders, the more effective is risk classification; this in turn results in a better marketplace for all.

Another type of adverse selection can occur when an insurer has less information than other competing insurance companies about the risk levels of its customers, c.f., Cather (2018). This can result in cream skimming, since the innovative insurer targets the best risks who, like cream in a container of fresh milk, rise to the top of a pool of policyholders.

Another classic type of information asymmetry is moral hazard. Insurers worry about insureds’ attitude toward safety; by purchasing insurance, insureds have the incentive to take on more risks (thus, increasing the probability of a risky event). For example, after purchasing of homeowners insurance, the insured may become lax in watching for fires (smoking in bed, not checking for frayed electrical wires). One way to mitigate this risk is through the installation of fire alarms.

Insurers also have to be wary of their own moral hazard. For example, if they acquire a protected variable such as political affiliation, then they have to be careful that this knowledge does not implicitly bias their pricing processes even if they do not use this information actively. One way to mitigate this risk is to simply avoid acquiring such protected information.

An implication of moral hazard is that people tend to increase their risk unless given incentives not to. Conversely, people may also reduce their risks when given incentives to do so. Indeed, much of modern risk management is predicated on introducing risk mitigation tools to reduce the impact of insured events. Classic examples include lower premiums for sprinkling systems in fire insurance and no smoker discounts in life insurance (Avraham,
Logue, and Schwarcz (2014)).

Insurers worry about traditional adverse selection and moral hazard because information asymmetries favor policyholders over insurers. In contrast, as emphasized by Schwarcz and Siegelman (2017), much of insurance law is designed to protect policyholders because of information asymmetries that favor insurers over policyholders. For example, policyholders are often insufficiently knowledgeable about an insurance policy terms and conditions, the insurers’ financial strength, and the appropriate type of policy for a consumer’s needs. Regulators are concerned that insurers may be able to exploit these deficits in policyholder information or sophistication by providing more limited coverage than policyholders believe they are purchasing, or by adopting excessively aggressive claims-handling strategies.

More recently, consumer advocates have been concerned that additional big data information, discussed more in Section 5.5, puts consumers at a disadvantage. For consumer advocates, more data information for insurers means that:

- Insurers can cherry pick at a granular level.
- Insureds do not have equivalent new tools to compare quality of policies and performance of insurance companies.

Consumer advocates argue that mandatory and de facto mandatory purchase of insurance means that free market competition is insufficient to protect policyholders.

3.2 Economic Efficiencies

Economists largely agree that a competitive market is an efficient one, c.f., Skipper and Klein (2000). Efficiency is achieved because competition forces buyers to pay their maximum demand price and forces sellers to charge their minimum supply price. Competition serves the best interests of consumers in that it provides insurers incentives to attract customers by reducing prices or improving insurance products. Competition policy is about applying rules to make sure companies compete fairly with each other.

One of the barriers to competition is asymmetric information; the insurance industry uses risk classification to cope with this potential problem. What could happen without risk classification? Because of the price differential we might see a reduced pool of insured individuals; this reflects a decrease in the efficiency of the insurance market. Extending this line of thought to multiple periods suggests an exodus of low risks that can lead to a death spiral of rising premiums and ends up unraveling the entire market, c.f., Dionne and Rothschild (2014).

However, by and large, insurers are allowed to classify risks. As argued by Tennyson (2007), a large body of academic research supports the conclusion that insurance markets
function in a workably competitive manner in the absence of rate regulation. Competition indicators include the number of insurers and their market shares, profitability, and price of their products. At least some markets for some countries (e.g., U.K. auto) generally exhibit the characteristics of a competitive market, FCA (2019) (Annex 3: International Comparisons).

Rate regulation can limit the insurers ability to classify risks and hence threaten competition. Tennyson (2007) describes two types of rate regulation regimes:

- *rate suppression* - reducing average rates for all consumers, and
- *rate compression* - reducing rates for some consumers (usually high-risks) relative to others (usually low-risks).

Both have negative consequences for insurance markets. Rate suppression runs the risk of driving average premiums below competitive levels, reducing insurer returns below a competitive rate of return. Rate suppression will distort insurance supply in the market, reducing competition in the long run. Rate compression can have similar effects by reducing rates for some consumer groups below competitive levels. As an example of evidence of the negative effects of rate regulation, in a classic article Blackmon and Zeckhauser (1991) document the negative effects of rate suppression and compression for the automobile market in Massachusetts.

### 3.3 Price Discrimination

The act of charging different prices for identical products is known in economics as *price discrimination*. To apply this to insurance, we need to specify that identical products also means identical production costs. We could, for example, have two auto policies that promise to pay exactly the same benefits for a loss. But, their prices may differ depending on risk factors such as the insured’s ability to drive and attitude towards risk, the type of vehicle itself (inexpensive family car versus a pricey sports car), the location where it is being driven (city versus rural), and so forth. So, the expected loss would be different causing the prices to differ. This type of *risk-based* price discrimination is the norm in insurance pricing. In contrast, Thomas (2012) uses the phrase *non-risk price discrimination* for the insurance situation where prices may differ for the same coverage and underlying risk characteristics.

Price discrimination is common in other industries. For example, airlines regularly charge higher prices for flights during the week (e.g., Monday to Friday) because these are typically taken by business travelers. This is an example of *first-degree price discrimination* where the price is based on the buyer’s willingness to pay. Second-degree discrimination involves quantity discounts, whereas third-degree discrimination reflects different prices for different
consumer groups, e.g., discounts for senior citizens (known as “honored citizens” in Portland). Price discrimination is not possible in a perfectly competitive market because there are many firms competing for the price, c.f., Lukacs, Neubecker, and Rowan (2016).

In the insurance industry, first-degree price discrimination is common in large commercial insurance where it is assumed that buyers are sophisticated and willing and able to negotiate prices. Third-degree price discrimination is common in personal insurance, at least in some jurisdictions such as within Europe and the United Kingdom. In particular, prices for renewing customers are often distinguished from risk-identical new customers, with different (usually lower) price offers made to new customers; “paying customers to switch.” To illustrate, the work in Adams et al. (2015) on general insurance auto confirms that some consumers pay much higher prices if they stay with the same insurer, particularly for a long period of time. This practice is motivated by so-called price optimization models that are described in Section 5.3.

For personal insurance, some jurisdictions allow price discrimination but others take a dim view of it. For example, in the early to mid-1800’s U.S. voluntary associations of insurers were organized in part to enforce uniform rates among the insurers. Uniform rates were desired so that rates were adequate to protect against insolvencies and were not unfairly discriminatory. From Miller (2009),

The primary concern with unfairly discriminatory rates, often stated at the time, was that rich and powerful insureds could unfairly negotiate lower rates than were being charged to less influential insureds, even though their degree of risk and underlying insurance costs did not warrant a lower rate.

Is price discrimination appropriate for insurance? Thomas (2012) summarizes five aspects of insurance that makes it different from other marketplaces.

(1) **Ability to discriminate.** Insurers can differentiate prices because of the quality of their data, the general confusion surrounding the pricing process, and the consumer’s inability to “re-sell” the product.

(2) **Price discrimination in insurance does not facilitate new markets.**

(3) **Price discrimination may undermine utmost good faith.** Laws mandate that customers provide information about their risks truthfully and, in many jurisdictions, insurers are also permitted to share information for the purposes of preventing fraud. If this information is used for other purposes, then over time this could undermine public acceptance of the doctrine of utmost good faith.

(4) **Price discrimination may undermine justifications for risk-related pricing.**
(5) **Distributional effects of price discrimination.** Allowing price discrimination may introduce cross-subsidies and have uneven effects on different parts of society.

Insurers may wish to use non-risk related factors to achieve legitimate business goals, such as maximizing profit or increasing customer retention. In these cases, firms may unwittingly discriminate, knowing only that a facially-neutral practice produces desirable outcomes. Section 5.3 describes the specific case of price optimization models where use of non-risk related factors is prohibited in many jurisdictions.

### 4 Actuarial Aspects of Rate Regulation

Section 1.1 provides an overview as to ways in which insurers discriminate; the focus of this section is on the pricing function. This is because actuaries are heavily involved, and hence influential, in pricing. Further, many regulations are geared towards pricing prohibitions, known as rate regulation. In addition, one can argue that prices are intimately related to whether or not someone is offered coverage (one could “price someone out of the market”) and the amount of coverage.

#### 4.1 Pricing

Like any business, pricing is critical in insurance. As described in Section 3, one aspect in which insurance differs from other industries is that the cost of the good is random and may not be known for many years after the sale of the product. This has led the actuarial profession to think deeply about what this “cost” entails.

Nonetheless, prices are often based on the cost of insurance. These are the costs of transferring a risk from the policyholder to the insurer. As described in standard actuarial textbooks such as Friedland (2013) and Werner and Modlin (2016) (see also Chapter 7 of the open source Loss Data Analytics), insurance costs consist of the (1) losses (compensation provided by the insurer for the insured claim), (2) expenses associated with the policy and claim, and (3) cost of capital (costs of keeping monies necessary to fund the insurance operation). Prices based on insurance costs are sometimes known as technical prices.

As described in the online supplement Frees and Huang (2021), many jurisdictions are silent on insurance rate regulations and so market prices are influenced by forces of supply and demand. As with other businesses, the cost of a product is an important but may not be the sole determinant of a price. Additional factors include the market availability of alternatives (e.g., costs of self-insurance, prices offered by competing firms) and marketing considerations such as customer loyalty. However, in jurisdictions where rate regulation
is prominent, prohibitions are in terms of technical prices. Because our focus is on rate regulations, we focus on cost-based technical prices.

Also from Frees and Huang (2021), many jurisdictions exhibit insurance rate regulations in one form or another. At the time of this writing, the U.S. is the country that most actively regulates rates and so we use this to motivate the discussion. From the U.S.-domiciled Casualty Actuarial Society’s Statement of Principles Regarding Property and Casualty Insurance Ratemaking (Principle 4), “a rate is reasonable and not excessive, inadequate, or unfairly discriminatory if it is an actuarially sound estimate of the expected value of all future costs associated with an individual risk transfer.”

In the U.S., insurance is regulated at the state level. The National Association of Insurance Commissioners (NAIC) is an organization that provides standards that states may adopt. As described in the model rating law NAIC (2010), the rule is that . . . Rates shall not be excessive, inadequate or unfairly discriminatory. It further defines an unfair discriminatory rate as . . . Unfair discrimination exists if, after allowing for practical limitations, price differentials fail to reflect equitably the differences in expected losses and expenses.

As an expectation, cost-based prices are naturally influenced by the choice of rating factors and this is where regulation comes into play. Regulators prohibit the use of certain variables - how do these prohibitions affect rating schemes?

4.2 Extent of Regulation

Insurance regulations may consist of applicable acts, statutes, regulations or any other binding authority (such as accounting standards and any regulatory guidance that is effectively binding), as described within the International Standards of Actuarial Practice (ISAPs) of the International Actuarial Association. In most jurisdictions, their enforcement is overseen by an insurance supervisor or regulator, many of whom follow the standards developed by the International Association of Insurance Supervisors (IAIS). According to their website, the IAIS “is the international standard-setting body responsible for developing and assisting in the implementation of principles, standards and other supporting material for the supervision of the insurance sector.” These include standards known as insurance core principles (ICPs): on insurer solvency, sales practices, agent licensing and policy forms, for example. Interestingly, there is no discussion within the ICPs on rate regulation.

The extent of insurance rate regulation varies by jurisdiction. At one end of the spectrum, the phrase active rate regulation means that the regulator is heavily involved in determining rates. This could mean government mandated rates in which regulators dictate the rates to be charged. Alternatively, regulators may only require approval of rates, either in advance or concurrent with policy offerings. Friedland (2013) (Chapter 27) summarizes the spectrum
of rate regulation. To illustrate, for the U.S., Borselli (2011) provides additional details including types of regulatory system organized by state and line of business. The other end of spectrum is competitive rating or open competition systems. Borselli (2011) compares active rate regulation to open compensation systems. He notes that historically many European countries operated under active rate regulatory environments but now regulators of European members states do not have the right to regulate insurance prices.

For more concrete descriptions, in a supporting document Frees and Huang (2021) we describe several major regulatory jurisdictions:

- The U.S. is the largest general insurance marketplace. It is also the most actively regulated jurisdiction with a coordinating body (the National Association of Insurance Commissioners) that develops model laws that *may* be adopted by individual states.
- The European Union is the second largest marketplace. It has a coordinating body (the European Commission) that develops legislative directives that *must* be implemented by member countries.
- China, Japan, and Australia, are the third, fourth and tenth, respectively, largest marketplaces. They illustrate the variety that even single country regulatory environments may exhibit regarding discrimination issues in insurance.

5 Prohibitions by Line of Business

In addition to jurisdiction, as emphasized by Avraham (2018), insurance prohibitions vary greatly by line of business. It is notable that the markets in which rate regulation is most common - automobile insurance, health insurance, workers compensation, medical malpractice, and homeowners’ insurance – are all markets in which insurance is mandatory or in which universal coverage is thought to be socially desirable, c.f., Tennyson (2007).

In commercial lines of insurance such as general liability and professional liability, the policyholder is a firm. As a general rule, insurance rate regulation tends to be absent from commercial insurance. In part this is because firms typically have more resources than individuals and so do not suffer the same imbalance of information asymmetry as described in Section 3.1. As exceptions to this rule, medical malpractice and workers’ compensation continue to be highly regulated. These two lines provide coverages that tend to be mandated by government regulations. Even though highly regulated, because the purchasers of insurance are generally organizations, discrimination issues are not as relevant. In the following, we focus instead on personal insurance.
5.1 Unisex Risk Classification

The European insurance marketplace was rocked in 2011 when the European Court of Justice concluded that any gender-based insurance discrimination is prohibited, European Union (2012). Prior to this ruling, gender was regularly routinely used for pricing insurance.

Broadly, what characteristics of this trait would lead society to prohibit its use for insurance discrimination? Referring to the Section 2.2 categories, sex at birth is certainly beyond the control of the insured. Insurers have economic motivation for using gender as a predictor because, for many lines of business, it exhibits helpful predictive abilities even though its causal nature can be debated. An important motivation for prohibiting gender as a rating variable is to limit the perpetuation of negative stereotypes, so that men and women would receive equal treatment in the access to and supply of all goods and services. Equality and respect for human dignity and human rights are among the core values of the European Union (EU), reflected in several EU directives targeting discrimination. Initially signed in 1957, Article 10 of the Treaty on the Functioning of the European Union states:

In defining and implementing its policies and activities, the Union shall aim to combat discrimination based on sex, racial or ethnic origin, religion or belief, disability, age or sexual orientation.

Like other major upheavals, this turning point was precipitated by other events. In the U.S., a series of legal rulings and new laws led to prohibitions based on gender for retirement systems, c.f., McCarthy and Turner (1993). The U.S. Supreme Court issued decisions that prohibit pension plans from using separate mortality tables for men and women to determine contributions and benefits.

1) From the case of Los Angeles Department of Water and Manhart (1978), employers cannot require women to make larger contributions to a pension plan in order to receive the same monthly benefits as similarly situated men.

2) From the case of Arizona Governing Committee for Tax Deferred Annuity and Norris (1983), women cannot receive lower monthly benefits than men who had made the same contributions (this case was based on a defined contribution plan).

These decisions were based on the 1964 Civil Rights Act that prohibits employment discrimination because of an individual’s race, color, religion, sex, or national origin. In 1986, the Equal Employment Opportunity Commission broadened the Supreme Court’s prohibitions by forbidding sex-based differences in any employee benefit, even if justified by differences in cost.
Another major event that preceded the 2011 ruling was a European Union Council Directive in 2000 that prohibited discrimination based on racial and ethnic origin, European Union (2000). Prior to this directive, some insurers required an additional premium based on the risk criterion of the applicant being a “foreigner,” c.f., Schmeiser, Störmer, and Wagner (2014). The 2011 ruling was based on European Union Directive 2004/113/EC, European Union (2004) (this earlier directive required equal treatment of men and women but provided an exception for the insurance industry). This ruling applies to all lines of insurance business; in contrast, for example, gender-based pricing of auto insurance is permitted in all but a handful of U.S. states (the exceptions being Hawaii, Massachusetts, Montana, North Carolina, Pennsylvania, and, in 2019, California). As part of the guidelines on the application of the 2011 ruling, the use of risk factors which might be correlated with gender, as long as they are true risk factors in their own right, is still permitted.

The retirement systems line of business is interesting because gender is an important predictor of longevity, c.f., Lemaire (2002). Women, in general, outlive men so they receive pension benefits over a longer period of time. For other lines of business such as personal auto, it is possible to find variables that provide a suitable substitute for gender, c.f., Ayuso, Guillén, and Pérez-Marín (2016). Section 6 explores the concept of proxy discrimination in more detail.

5.2 General Insurance and Credit-Based Scoring

An individual’s credit history has long been used in commercial lines of insurance and in life insurance. As described by Brockett and Golden (2007), “Although it has been known since at least 1949 that credit history is related to driving accidents, the advent of high capacity, high-speed computers has made massive personal credit files available, and has made it feasible to routinely use this credit information for predicting insurance losses in personal lines of property and casualty insurance.”

From FTC (2007), general insurers in the U.S. started to use credit history information for automobile pricing in the early 1980’s. It became more routine with the development by Fair Isaac Corporation (FICO) scores in the mid 1990s, first for homeowners and then for auto. According to FICO, in the absence of state prohibitions, 95 percent of automobile insurers and 85 percent of homeowners insurers employ insurance scores in either the underwriting or rating process (NAIC 2012a), see also Morris, Schwarz, and Teitelbaum (2017).

Credit-based insurance scores, or simply insurance scores, are similar to widely known credit scores in that both rely upon an individual’s credit history. This credit history includes prior credit performance (e.g., late payments), current levels of indebtedness (e.g., bankruptcy), length of credit history (e.g., age of oldest account, average age of all ac-
counts), pursuit of new credit (e.g., new accounts, mortgages), and types of credit used (e.g., department, travel, major bank credit cards). However, credit scores predict the risk of credit delinquency and so measures the financial well-being of a consumer. In contrast, an insurance score is designed to predict insurance losses and so assesses how well individuals manages their money.

Credit-based insurance scores summarize an individual’s personal financial history; they do not exhibit the characteristics described in Section 2.2 that would lead them to being described as sensitive or suspect. However, as emphasized by Morris, Schwarcz, and Teitelbaum (2017), insurance scores are regulated because they potentially correlate with suspect classifications, in particular race and income. For this reason, in the U.S. most states regulate insurers’ use of insurance scores in auto and home insurance, and a few states ban their use altogether (Avraham, Logue, and Schwarcz (2014), Avraham (2019)).

Credit-based insurance scores provide a natural example where the ability to predict insurance losses is well established (statistical discrimination) but the causal nature is uncertain. As noted by Brockett and Golden (2007), a poor credit score may not create (cause) an insured loss but it is a measure of underlying biological and psycho-behavioral traits that do affect insured losses. However, from Morris, Schwarcz, and Teitelbaum (2017), this is inconsistent with the fact that two of the major drivers of credit risk are unemployment and health problems, neither of which seems to reflect irresponsible behavior such as reckless driving or lack of fire safety. So, although both sources re-affirm that credit-based insurance scores provide a sound platform for predicting insurance losses, the causal nature remains unclear.

5.3 General Insurance and Price Optimization

Technical prices, that are based on expected claims, provide the foundations for most lines of general insurance, at least on the non-commercial, or personal, side. Traditionally, informal judgement has been used to adjust technical prices to become market prices; these adjustments are (i) for consistency among factors, plans, and over time, (ii) for competitors rates, and (iii) for impact on retention, c.f., CAS (2014). Price optimization refers to a systematic approach for making adjustments to traditional cost-based technical prices that incorporates customer demand.

Technical prices can be thought of as based on single-period models that focus on costs of insurance including claims and expenses. In contrast, the price optimization approach incorporate models of retention as well as prices of competitors typically by looking over several periods. For example, if an insurer raises prices, then that insurer can expect lower retention; the amounts depend on how sensitive the consumer is to price changes and the
availability of the same coverage from the competition. By looking over several periods, price optimization models can tune prices to achieve an insurer’s long-term goals, such as profitability or development of market share.

From an insurer’s point of view, the use of price optimization tools is simply a sound business practice that is widely adopted in many industries, including retail and travel. Price optimization moves insurance pricing beyond expected costs to behavior including price sensitivity. At the individual consumer level, it may be that an insurer prices differently two consumers with the same risk profile because their anticipated price sensitivity differs, c.f. Section 3.3. Price sensitivity matters because it affects consumer retention and acquisition expenses for new business are generally higher than expenses for retaining a customer, c.f., CAS and Force (2015).

However, consumers have taken a dim viewpoint of price optimization (see a summary in CAS and Force (2015)). On the one hand, the ability to identify loyal customers suggests that these are the customers who would enjoy lower premiums because of the lower expenses associated with them. On the other hand, these are exactly the customers who are likely to stay (and remain loyal) when faced with price increases. Some critics argue that price sensitivity practices impose an unfair penalty on customer loyalty. Customers more likely to be loyal are less likely to shop for alternatives. Insurers will identify this tendency and so impose price increases on customers, not for their tendency to have high claims but rather for their tendency to be loyal.

Other critics argue that price optimization has been developed to increase insurers’ profits by raising premiums on individuals who are less likely to shop around for a better price, and many of these people are low-income consumers. Consumer advocates assert that deviation from cost-based ratemaking through price optimization will disfavor those consumers with fewer market options, less market power and less propensity to shop around in particular, low-income and minority consumers. Thus, although insurers may be optimizing neutral objectives, the result of their actions can result in unintentional proxy discrimination.

Swayed by these arguments, many U.S. insurance state regulators have banned price optimization in personal lines insurance. As another example, price optimization and price discrimination is not illegal in Australia but it does give rise to consumer unease and is being scrutinized by regulators, ESL (2018).

5.4 Life Insurance and Genetic Testing

Genetic testing involves a type of medical test that examines chromosomes, genes, or proteins. The results of a genetic test can confirm or rule out a suspected genetic condition or help determine a person’s chance of developing or passing on a genetic disorder. There are
many different purposes for testing, including medical (such as diagnosing a genetic disease or predicting disease risk) and non-medical (such as confirming parentage or forensic investigation). Hundreds of genetic tests are currently in use and more are being developed, see, e.g. Born (2019).

Information from genetic tests is potentially sensitive. Following the structure in Section 2.2, the main reasons are because they are not under the control of an individual nor, in most cases, do they change over time. Only in rare instances (such as Huntington’s disease) is a genetic condition known to cause an insured event such as death. When thinking about the standards of perpetuating negative stereotypes and historical precedence, the genetic tests themselves are new (and developing), so the historical impact of a specific test is minimal. Nonetheless, as noted by Avraham, Logue, and Schwarcz (2014), “Genetic discrimination in the context of health, life, and disability insurance immediately evokes Nazi Germany and its obsession with promoting the reproduction of more ‘genetically desired’ people and eliminating ‘genetically defective’ individuals.”

Statistical discrimination is another important attribute. Earlier, Lehtonen and Liukko (2011) wrote “At least for the time being, genetic information is in most cases neither statistically nor economically significant for risk assessment from the insurance companies’ point of view. The exceptions are the rare single-gene diseases, such as Huntington’s disease, which inevitably or very likely result in death.” As of this writing, this remains the case (c.f., Vukcevic and Chen (2018)); today, it is likely that including results from genetic testing will not materially alter an insurer’s prices. However, insurers believe that this will change over time; that is, predictive ability of genetic testing will increase over time and will become salient in at least the life, disability, critical illness, and long-term care insurance marketplaces.

Insurers worry about genetic testing information because of information asymmetry concerns. Like the purchase of life insurance, the decision to undergo genetic testing is voluntary. When a potential policyholder has information about his or her health that is not shared with the insurance company, this could lead to anti-selection where poorer risks purchase more insurance and better risks purchase little or no insurance. From an insurer’s viewpoint, one solution would be to allow insurers to require genetic testing, just as they are allowed to evaluate other aspects (e.g., weight, hypertension, and so forth) of a person’s health. There is some evidence that prohibitions on using genetic testing information may materially affect insurer’s claim costs, see e.g. Lombardo (2018).

In policy debates, arguments have been made for the position that genetic information is special and must therefore be treated differently from other types of medical information (sometimes known as genetic exceptionalism). One way that genetic testing differs from, e.g., blood pressure, is through the impact that it has on a person’s willingness to undergo the
testing for fear of being denied life insurance. As summarized by Prince (2019), “Empirical evidence shows that fear of genetic discrimination has led individuals across the globe to refuse to participate in genetic research projects or to fail to undergo recommended clinical testing.” Nonetheless, this may be simply due to the evolving nature of the science of genetic testing. For an analogy to underscore this point, Born (2019) noted that “… over time, other types of medical tests – e.g., tests for cholesterol levels – were first considered controversial when initial evidence showed a wide variation in predicted value.”

The social impact depends on the line of insurance business. In health insurance, the impact of genetic testing is less pronounced because many leading countries in the world offer government-provided health insurance or mandate the purchase of health insurance. Even in the U.S., that does not have government provided health insurance, results of genetic testing are not permitted under the Genetic Information Nondiscrimination Act (GINA). This act prohibits covered health insurers (and employers) from discriminating on the basis of genetic information that includes genetic test results, family medical history, and use of genetic services.

Some international conventions recommend restricting the use of genetic information for insurance purposes. The Council of Europe’s Convention on Human Rights and Biomedicine prohibits the performance of genetic testing as a condition for entering into an insurance contract, (c.f., Lehtonen and Liukko (2011)). The United Nations Educational, Scientific, and Cultural Organization (UNESCO) in 1997 issued a Universal Declaration on the Human Genome and Human Rights. This was followed by a 2003 declaration that argued that genetic data and biological samples should not be accessible by insurance companies, among other actors (c.f. Prince (2019)).

While many countries have specific laws covering genetic testing, most of the regulations are not very detailed. Table 5.1 summarizes genetic testing regulations, from Klein (2017). Joly et al. (2020) provides another perspective on cross-country comparisons. Not only the science, but also the insurance regulation, of genetic testing continues to evolve. Several jurisdictions have passed or are considering legislative changes in the use of genetic testing information in underwriting insurance. For example, Canada passed federal laws in 2017 banning the use of all genetic information for business purposes, see e.g. Lombardo (2018). Within the U.S., Born (2019) documents recent proposals in the state of Florida. Further, in July 2020, Florida has passed a law that prohibits life insurers & long-term care insurers from canceling, limiting, or denying coverage, or establishing differentials in premium rates based on genetic information. As noted in Table 5.1, Australia has been active in considering genetic testing legislation.

5.5 Big Data

As with all institutions, insurers are redefining the way that they do business with the increasing capacity and computational abilities of computers, availability of new and innovative sources of data, and advanced algorithms that can detect patterns in insurance activities that were previously unknown. Sections 6.3 and 6.4 summarize how these advanced algorithms can be used to mitigate discrimination issues.

Conceptually, Big Data does not alter the fundamental issues of insurance discrimination. This point was emphasized in Swedloff (2014), entitled “Risk Classification’s Big Data (R)evolution.” One can think of credit-based scoring and price optimization as simply forerunners of a long-term trend by insurers to gather more and more data about their current and potential customers. One might hope that machine-driven algorithms would eliminate human biases but, as documented by Barocas and Selbst (2016), these algorithms inherit the prejudices of authors of the algorithms and prior decision-makers. As another example, Bartlett et al. (2019) find that the use of algorithmic decision-making of mortgage loans in the U.S. results in significant proxy discrimination of Latin and African-American borrowers although significantly reduces discriminatory practices of face-to-face lenders.

Yet, Big Data is changing the way that insurers do business. With respect to insurance discrimination, Swedloff (2014) argues that the two main aspects of change are privacy and proxy discrimination. On the privacy front, some of this detailed information is provided.
voluntarily by individuals to insurers and suggesting to some that it not be treated as sensitive. This includes information from global position systems (GPS) that we put in our cars that underpin telematics, comparable devices for our homes (the Internet of Things), devices that we wear to improve our health, and so forth.

Still, insurers may also use other information that is not provided directly by individuals. Privacy issues are raised any time a carrier classifies risks on intimate, personal information, like HIV status, marital status, sexual orientation, or genetic information. Although not an insurance case, Swedloff (2014) discusses the highly publicized event where Target, a large U.S. department store, used analytics to predict which of its customers were pregnant. This information was passed on to the marketing arm who sent coupons for maternity clothing, nursery furniture, and the like, to women who were likely to be expecting a child. That is, without asking any customers about their pregnancy status or harvesting that data in particular, Target was able to predict extremely sensitive and personal information about its customers. Consumer advocates fear that similar information, such as where we go, movies that we watch, telephone calls and texts that we make, would be of interest to insurers ostensibly to be used for understanding consumers attitudes towards risk and the likelihood of making insurance claims.

Proxy discrimination, introduced in Section 2.3, occurs when a surrogate, or proxy, is used in place of a prohibited trait. As originally conceived, this proxy is a facially neutral trait, such as the size of an automobile’s engine being used as a proxy for gender. In the world of Big Data, an equally important issue is that complex algorithms are being developed using literally thousands of traits (in the simple Target example, the analyst used only 25 traits to develop an effective pregnancy score). Thus, as emphasized by Prince and Schwarcz (2020), proxy discrimination may be unintentional; moreover, the insurer may not even be aware that it is engaging in discriminatory behavior due to the opaqueness of machine-driven algorithms. Proxy discrimination is particularly important for actuaries and so is further discussed in Section 6.

Although consumers may benefit from a marketplace where insurers can more accurately assess risks, there is also a potential loss of transparency in insurance pricing. There already exists a low level of consumer understanding and a low level of consumer engagement with insurance purchases. More complex data algorithms will impede efforts at transparency. As discussed by Richman, Rummell, and Wuthrich (2019), machine learning models are often more complex and less transparent than traditional models. Moreover, massive data sets and complex models do not make life easier for regulators. Insurance regulators need to review rating plans that incorporate complex predictive models. Many jurisdictions do not have sufficient in-house actuarial expertise to review such filings.
For a final note on Big Data, some have expressed a concern that highly individualized or personalized rates lose the benefit of risk pooling, e.g., ESL (2018) and Meyers and Van Hoyweghen (2018). Although this could be a problem for some portfolios, most insurance systems are based on diversification of pools of unrelated (independent) risks. This type of diversification does not go away when the risks are different as long as they are priced properly.

5.6 COVID-19

A pandemic is a global outbreak of disease and in early 2020 the world has seen the onslaught of a new coronavirus dubbed COVID-19, short-hand with the ‘CO’ for ‘corona,’ ‘VI’ for ‘virus,’ and ‘D’ for disease. The ‘19’ is because it was first identified in 2019 (from the outbreak in Wuhan China). As with other parts of global economy, the disease has rocked the insurance industry. The lines of business most affected on the commercial side include workers’ compensation, business interruption insurance, cyber liability, general liability, and event cancellation as well as health and travel insurance on the personal side. see e.g. Fannin (2020). Interestingly, automobile insurance claims have dramatically reduced (for the first part of 2020 at the time of this writing) due to travel restrictions; people are driving less and getting into fewer accidents.

Prohibiting Insurance Discrimination Based on COVID-19 Diagnosis. Insurance legislation is being introduced to prohibit discrimination based on the diagnosis of this disease. For example, the State of Wisconsin passed a law on 15 April 2020 that includes the following:

This bill prohibits insurers that offer an individual or group health benefit plan, pharmacy benefit managers, or self-insured governmental health plans from doing any of the following based on a current or past diagnosis or suspected diagnosis of COVID-19: establishing rules for the eligibility of any individual, employer, or group to enroll or remain enrolled in a plan or for the renewal of coverage under the plan; cancelling coverage during a contract term; setting rates for coverage; or refusing to grant a grace period for payment of a premium that would generally be granted.

As another example, on 14 April 2020, the Australian Competition and Consumer Commission has granted interim authorization to the Financial Services Council and its members to ensure front line healthcare workers are not excluded from coverage due to exposure to COVID-19. That means life insurers cannot use the exposure to COVID-19 as a factor for
pricing or applying risk exclusions to any new policy. It is likely that other legal jurisdictions will undertake similar actions. From a narrow actuarial perspective, this legislation is about coverage and rating and so is important for actuaries. Further, in absence of legal restrictions, a competitive market would use diagnosis of COVID-19 like any other part of medical history, potentially predictive of future insurable events.

More broadly, this legislation has several implications. For example, in absence of this legal restriction, rates may well increase for grocery store workers, due to their exposure and increased suspicion of a diagnosis of COVID-19. Is this in the best interest of society? To sharpen understanding of the social and economic considerations presented in Sections 2 and 3, we now reflect on these principles in terms of COVID-19.

Social Justice Considerations of COVID-19 Insurance Prohibitions. By its very global nature, a pandemic brings out the social responsibility of an insurance pool described in Section 2.1.1. The line of business affected by COVID-19 may be viewed as social/public good (e.g. health insurance) or as an economic commodity (e.g., life insurance) but the responses to COVID-19 are certainly social. Just as when you build a dam it benefits everyone who lives in the areas (not just those who make contributions towards building it), in the same way societal measures for disease prevention (e.g., social distancing) are borne by the entire population.

Section 2.2 introduced variable attributes that influence fairness for insurance purposes. For a COVID-19 diagnosis:

- **Control.** Individuals have few controls as to whether they have disease symptoms due to its widespread impact on society.
- **Mutability.** The variable may change over time but not in a good way.
- **Causality/Statistical Discrimination.** For those that have recently contracted the disease, there is a known pathway to heightened mortality risk and healthcare costs. For those diagnosed with disease but have recovered, there are no known additional risks to mortality nor to morbidity.
- **Limiting or Reversing the Effects of Past Prejudice.** This is not an issue as COVID-19 is a new disease.
- **Inhibiting Socially Valuable Behavior.** If insurers were allowed to rate based on disease symptoms, it is likely that many would refuse testing which would inhibit scientific progress in addressing the disease, similar to genetic testing.

**Proxy Discrimination.** In the U.S., it is known that COVID-19 affects African-Americans more than other ethnic groups and that COVID-19 mortality rates are related to age. Thus,
insurer discrimination based on contracting COVID-19 could be viewed as an indirect path to race and, where pertinent, age discrimination.

Economic Considerations of COVID-19 Insurance Prohibitions

- **Adverse Selection.** It is likely that individuals would know about whether they had symptoms of COVID-19 without going through formal testing - unknown to the insurer. This creates the potential for adverse selection.

- **Competition.** It is unlikely that any insurer will have private knowledge about the nature of the COVID-19 disease suggesting that marketplace competition is not an issue. However, some insurers may elect to pull out of the marketplace (such as with travel insurance), meaning that lack of supply may increase prices.

- **Price Discrimination** is not likely to be an issue with COVID-19.

Summary of COVID-19 Insurance Prohibitions For a pandemic, the weight of evidence suggests that societal concerns dominate and that a prohibition based on diagnosis, real or suspected, of COVID-19 is warranted. As insurers’ lack data about its predictive abilities, it is unlikely that competition will be affected. Prohibitions of this nature increase consumer confidence in the insurance system. At a hopefully not too far date in the future, the COVID-19 will lose its pandemic status and become another disease that we have to deal with. At that time, special legislative actions for COVID-19 will lose their appeal.

6 Proxy Discrimination

Proxy discrimination, when a seemingly innocuous variable is correlated with a protected variable, can be a problem because it produces the same outcomes that would be obtained in the absence of restrictions based on directly predictive traits, c.f., Prince and Schwarcz (2020). This is true whether or not the surrogate is opaque to the insurer and the regulator.

6.1 Strategies for Mitigating Proxy Discrimination

Historically, the focus has been on introducing regulation that prohibits the use of protected variables, such as race, or surrogates thought to be proxies for protected variables, such as credit-based insurance scores. More recently and providing a greater challenge is how to mitigate proxy discrimination when the proxies are produced by opaque machine learning algorithms based on many variables. There are several strategies that policymakers can use to limit this latter type of discrimination, none of which are ideal.
1. **Community Rating.** At one end of the spectrum, proxy discrimination can be completely eliminated by removing the insurer’s ability to discriminate entirely. This is the case in community rated plans where all policyholders pay the same price such as common in social insurance schemes.

2. **Approved Variables.** Another option is to specify variables that may be used instead of variables that may not be used. This is the strategy taken in the U.S. individual health insurance market under the Affordable Care Act (ACA). Specifically, insurers may vary rates based on only four factors, (1) whether a plan covers an individual or family, (2) geographic area, (3) age, and (4) smoking status. As described by Prince and Schwarcz (2020), the ACA prohibits discrimination on the basis of prior health history, pre-existing conditions, and sex.

3. **Actuarial Justification.** A third alternative is to restrict the use of protected variables, such as race, religion, and political affiliation, and to further limit the use of rating variables to only those that are actuarially justified, that is, statistically discriminatory. This is the case of the U.S. rules on unfair discrimination where variables induce price differentials that “reflect equitably the differences in expected losses and expenses.” There are usually data disclosure requirements for actuarial justification. For example, in the case of insurance based on age discrimination in Australia, “the Commission and the President can require the disclosure of the source of the actuarial or statistical data”. And for the case of insurance based on sex discrimination in Australia, there are clients related data disclosure provisions, see the Appendix of Frees and Huang (2021) for further details.

4. **Limited Prohibitions.** A fourth strategy is to only restrict the use of protected variables (including their proxies) such as gender. This is the model followed by the European rules. However, as noted in Frees and Huang (2021), European regulation permits the use of risk factors correlated with gender as long as they are risk factors in their own right.

5. **No Restrictions.** At the other end of the spectrum, an option is to have no prohibitions. This is the case for most lines of commercial insurance.

Within this broad spectrum, there are many variations that regulators could consider particularly for the third and fourth strategies that permit some insurer discretion. One possible solution is to focus on transparency-oriented reforms that require insurers to disclose information on how their algorithms are working and possibly the sources of their data.
6.2 Linear Model Strategies

Another possible solution is to require insurers to use only variables that contain no protected information. To see how this might work in practice, consider data that we can represent as \( y \), an outcome of interest such as an insurance claim and a set of predictor or rating variables. Further decompose the rating variables into components, those that are permitted, or not protected, by the regulators \( X_{NP} \) (non-protected variables) and those that are potentially contentious or protected, \( X_P \). Following the work of Aseervatham, Lex, and Spindler (2016), we can consider \( y \) to be an auto insurance claim, \( X_P \) an indicator for gender, and \( X_{NP} \) to be a collection of other variables that includes age, type of car, location, and so forth.

In absence of regulatory restrictions, the actuary would consider all variables. For ease of interpretation, consider a “full” linear regression model, \( y = 1 \beta_0 + X_P \beta_1 + X_{NP} \beta_2 + \epsilon \), with predictors of the form

\[
\hat{y}_{full} = 1 b_0 + X_P b_1 + X_{NP} b_2.
\] (1)

In the presence of regulatory restrictions, the actuary could consider a restricted model, \( y = 1 \beta_{0,1} + X_{NP} \beta_{2,1} + \epsilon_1 \), with predictors of the form

\[
\hat{y}_{restricted} = 1 b_{0,1} + X_{NP} b_{2,1}.
\] (2)

For a sensitive variable \( X_P \) to be the subject of contention, it often is correlated with an outcome \( y \). So, one might expect for there to be a drop in the predictive ability when moving from the full information predictors \( \hat{y}_{full} \) to the restricted ones, \( \hat{y}_{restricted} \). In point of practice, often there is a strong relationship of \( X_P \) with the other predictor variables \( X_{NP} \). When \( X_P \) is dropped, the other variables serve as proxies for the omitted variable. For example, in their study, Aseervatham, Lex, and Spindler (2016) found that this was largely the case, the interesting exceptions being for younger and older drivers. As another point of practice, if a variable is dropped (such as gender), then it is likely that insurers may seek to incorporate new variables that also serve as proxies (“gender-like”) for the protected variables.

When a variable is dropped, the impact of the other factors changes, as quantified by the regression coefficients moving from \( b_2 \) to \( b_{2,1} \). This is not always desirable and so, to mitigate this drawback, Pope and Sydnor (2011) proposed an alternative predictor

\[
\hat{y}_{PS} = 1 b_0 + \bar{X}_P b_1 + X_{NP} b_2,
\] (3)

where \( \bar{X}_P \) is the average over the protected variables. Here, the coefficients \( b_0, b_1, \) and \( b_2 \) are from the full model. These predictors are blind to the protected variables in that two
individuals who differ only in their protected characteristics will receive the same predicted value from the model. However, as with \( \hat{y}_{full} \) and \( \hat{y}_{restricted} \), \( \hat{y}_{PS} \) can be correlated with the protected variables. In words, the average predicted values will vary across protected groups because of differences in other characteristics across groups. Please note, the Pope-Sydnor model is not restricted to linear models, as shown in Lindholm et al. (2020).

As another option, there may be instances when the actuary would like to have a rating scheme that is totally unrelated to any sensitive or protected variables. For example, one can imagine using only that information that is uncorrelated to a set of protected variables under contention.

To this end, create a set of variables that are uncorrelated to \( X_P \) by defining \( X_1 = (1 \ X_P) \), the projection matrix \( Q = I - X_1 (X'_1 X_1)^{-1}X'_1 \) and the transformed variables \( X^*_{NP} = Q X_{NP} \). Then, with the new variables, one uses the usual least square procedures to get \( b^*_2 = (X^*_{NP} X^*_{NP})^{-1} X^*_{NP} y \). Some standard matrix algebra shows that \( b^*_2 = b_2 \), that is, the regression coefficients from the transformed variables equals the regression coefficients in the full model. See for example Frees (2009), page 141. From this, the predictors are

\[
\hat{y}_{FH} = 1 \bar{y} + X^*_{NP} b_2.
\] (4)

By construction, these predictors are uncorrelated with the sensitive, protected, variables.

### 6.3 Empirical Example

To see how these strategies might work in a real insurance context, we analyze 4624 claims from Australian automobile insurance drawn from De Jong and Heller (2008). So that our work can be easily replicated, we use the data from the \( \mathcal{R} \) package \texttt{CASdatasets} that slightly differs from the de Jong and Heller book in the coding of the variables. Statistical code, using the freely available software \( \mathcal{R} \) is in the Appendix of a supporting document Frees and Huang (2021).

For this analysis of claims severity, \texttt{ClaimAmount}, we focus on a potential protected variable, \texttt{Female}, indicating if the policyholder is female. Other variables relevant to claims severity for these data are \texttt{VehValue}, the vehicle value in thousand of Australian dollars, and \texttt{DrivAge}, the age and employment status of the policyholder. A preliminary examination of the data (not included here but available, for example, in De Jong and Heller (2008)), show that the distribution of claims is skewed. From this and customary industry practice, we fit a gamma distribution with a logarithmic link. The analysis summarized in Table 1 shows that \texttt{Female} is an important predictor of claim amount.

This model could be readily used for predicting claims severity. For illustrative pur-
Table 1: Gamma Regression Model 1 Summary

|                      | Estimate | Std. Error | t value | Pr(>|t|) |
|----------------------|----------|------------|---------|----------|
| (Intercept)          | 7.984    | 0.093      | 85.580  | 0.000    |
| VehValue             | -0.012   | 0.022      | -0.521  | 0.602    |
| DrivAge old people   | -0.411   | 0.104      | -3.946  | 0.000    |

| DrivAge young people  | -0.199   | 0.096      | -2.073  | 0.038    |
| Female               | -0.179   | 0.052      | -3.450  | 0.001    |

poses, the left-hand panel of Figure 1 shows the distribution of fits for the same portfolio of policyholders used to fit the data; the right-hand panel shows the distribution by gender.

![Figure 1: Distribution of Claim Amounts](image)

The right-hand panel of Figure 1 shows significant differences by gender. To address this, the model was re-fit excluding gender and the fitted values are labeled as Model 2. As another alternative, we fit a model using the orthogonalized versions of the VehValue and DriveAge variables, making each variable uncorrelated with Female. This results in Model 3. Then, we developed a proxy for the probability of being female, using automatic variable selection techniques, with VehValue and DriveAge as inputs but also including additional variables in the dataset that were not helpful predictors of ClaimAmount. We added this

predictor to Model 2 and to Model 3, resulting in Models 4 and 5, respectively. Finally, we developed the Pope-Sydnor predictors from Model 1, the results of these fits are labeled as Model 6. This development is detailed in an Appendix of Frees and Huang (2021).

Table 2 summarizes results from the first five models (the repetition of Model 1 is included for comparison purposes). From Model 1, females have significantly lower claims. Similarly, from Models 4 and 5, a higher probability of being female implies a lower expected claim amount. From the AIC goodness of fit statistics, Model 1 is the best fit. Models 2 and 3 are similar and exhibit a markedly worse fit than Model 1. It is interesting that Model 3 does not perform that much worse than Model 2; that is, removing effects of gender from the other predictor variables does not do that much damage to the overall model fit. Models 2 and 3 are significantly improved by including the proxy for being female, as shown in Models 4 and 5.

Table 3 shows the means of the fitted values by gender under each model, including the Pope-Sydnor predictors. These fits are rescaled so that they have the same mean, thus promoting comparability. Figure 2 expands upon this by showing the corresponding distributions. The base Model 1 displays the biggest discrepancy between male and female distributions, suggesting that corresponding prices calculated using this procedure would be the largest among the alternatives considered. Model 2 is the only fitting procedure that does not require knowledge of the protected variable Female. Fits from Model 3 are very similar to those of Model 2 (it turns out that the Spearman correlation between fits is 0.994); further, Model 3 is attractive because it only uses predictors that are uncorrelated with the protected variable Female. The fits from Model 4 uses the same base variables as Model 1 but replaces the protected variable with a proxy. Coefficients of the proxy are determined using the protected variable but, once the coefficients have been determined, the proxy depends only on known covariates, not the protected variable. As with the comparison between Models 2 and 3, Model 5 is similar to Model 4 but uses only covariates uncorrelated to the protected variable (in addition to the proxy variable). Using Model 6, two individuals who differ only in gender will have the same fitted values from the model. However, it does

6.4 Machine Learning Approaches

Recent years have seen an increasing trend in using big data and machine learning techniques in various actuarial practices, as introduced in Section 5.5. They are usually praised for superior out-of-sample forecasting performance, but can also be opaque in insurance discrimination. Mehrabi et al. (2019) identified two potential sources of unfairness in machine learning: biases in data and algorithms. Data (especially big data) can be heterogeneous and creates bias in many different ways, which may lead to unfair results when a model learned from biased data. Algorithms may also lead to unfair decisions even when data are unbiased. To the best of our knowledge, there has been limited research in the actuarial/insurance literature discussing how to measure and manage discrimination using machine learning approaches. For example, Loi and Christen (2019) provide an ethical analysis of private insurance discrimination and fairness in machine learning. They distinguish morally permissible and impermissible forms of statistical discrimination in private insurance and derive some ethical implications for the use of machine learning techniques in the insurance context.
Although the motivating applications are typically not insurance related, the machine learning field has seen an explosion of research on fairness. See, for example, the survey papers Zliobaite (2015), Romei and Ruggieri (2014), Mehrabi et al. (2019) and Chouldechova and Roth (2018). This literature provides discussions and debates on how to define fairness of predictive models and how to measure the performance in terms of discrimination. For example, Kleinberg, Mullainathan, and Raghavan (2016) formalize three core fairness conditions in algorithmic classification that correspond to notions of fairness: calibration within groups, balance for the negative class, and balance for the positive class. They find that except in highly constrained cases, there is no method that can satisfy the three conditions simultaneously. The results suggest thinking about the trade-offs between the notions of fairness.

Following Mehrabi et al. (2019), we summarize three ways for discrimination prevention: pre-processing, in-processing, and post-processing. Data pre-processing removes the discrimination information from the historical data (target or input variables) and then applies regular machine learning approaches for model estimation, for example see Kamiran and Calders (2012) and Calders and Zliobaite (2013). Most of the linear model strategies introduced in Sections 6.2 belong to this category. In-processing techniques modify the learning algorithms by incorporating changes into the objective function or adding additional constraints to remove discrimination in the model learning phase, for example, see Kamishima et al. (2012). Post-processing modifies a fitted regular model to remove discrimination. For example, Kamiran, Calders, and Pechenizkiy (2010) post-processing decision trees with discrimination-aware pruning and relabeling of tree leaves. The discrimination-free pricing model introduced in Pope and Sydnor (2011) also belongs to this category.

Machine learning approaches generally require knowledge of both protected and non-protected variables. However, for legal or commercial reasons organizations (including insurers) may not hold data of protected variables, such as gender, race and ethnicity, which poses challenges to mitigating discrimination, c.f., Miller (2009). Veale and Binns (2017) introduces and discusses three potential approaches to deal with this problem, including (1) having trusted third parties to store data necessary for incorporating fairness constraints in modelling, (2) building collaborative online platforms to allow diverse organisations to share and access knowledge required to promote algorithmic fairness, and (3) using unsupervised learning and pedagogically interpretable algorithms to incorporate fairness hypotheses for further selective testing and exploration.

Despite the explosion of interest and volume of work that has been produced and published in recent years, the theory and application of discrimination-aware machine learning is still in a nascent state, especially in the context of insurance practice.
Understanding the insurance prohibitions landscape is important for actuaries and other financial analysts. Actuaries are heavily involved in setting of insurance prices. They are also often influential in determining the scope of insurance contractual coverages as well as whom the company insures, both initially and at renewal. Our position is not that actuaries should dictate whether or not use of information should be restricted or prohibited. Rather, choices regarding insurance prohibitions involve policy choices that should also involve legal and economic scholars, as well as government representatives and advocates for the industry and for consumers. Actuaries can make important contributions to these discussions by quantifying the financial impact of policy alternatives. This article helps actuaries to present financial cost recommendations in a meaningful way by summarizing different perspectives that other participants may entertain when considering insurance prohibitions.

Extended Abstract

The insurance industry is built on risk classification, grouping insureds into homogeneous classes. Through actions such as underwriting, pricing and so forth, it differentiates, or discriminates, among insureds. Actuaries have responsibility for pricing insurance risk transfers and are intimately involved in other aspects of company actions and so have a keen interest in whether or not discrimination is appropriate from both company and societal viewpoints. This paper reviews social and economic principles that can be used to assess the appropriateness of insurance discrimination. Discrimination issues vary by the line of insurance business and by the country and legal jurisdiction. This paper examines social and economic principles from the vantage of a specific line of business and jurisdiction; these vantage points provide insights into principles. To sharpen understanding of the social and economic principles, this paper also describes discrimination considerations for prohibitions based on diagnosis of COVID-19, the pandemic that swept the globe in 2020.

Insurance discrimination issues have been an important topic for the insurance industry for decades and is evolving in part due to insurers’ extensive use of Big Data, that is, the increasing capacity and computational abilities of computers, availability of new and innovative sources of data, and advanced algorithms that can detect patterns in insurance activities.
that were previously unknown. On the one hand, the fundamental issues of insurance dis-
 crimination have not changed with Big Data; one can think of credit-based insurance scoring
and price optimization as simply forerunners of this movement. On the other hand, issues
regarding privacy and use of algorithmic proxies take on increased importance as insurers’
extensive use of data and computational abilities evolve.
1 Regulation by Jurisdiction

1.1 U.S. Insurance Discrimination Legal Environment

The U.S. is the largest general insurance marketplace, to illustrate, it comprised about 37% of the 2017 world market (in terms of gross direct premiums, see Table 7 of GIAJ (2019), SwissRe (2018)). In the U.S., discrimination laws and regulations affecting insurance appear at both the federal (national) and state level.

1.1.1 U.S. Federal Laws and Regulations

There is a host of federal laws directing towards mitigating discrimination in employment. These laws take a broad view of employment and include fringe benefits such as retirement benefits. As noted in Section 5.1 of Frees and Huang (2020), of Frees and Huang (2020), these laws, such as the 1964 Civil Rights Act, are now known to limit the use of gender in retirement benefits. For other limitations, the U.S. Equal Employment Opportunity Commission, charged with enforcing these laws and regulations, decomposes discrimination into the following types: age, disability, equal pay/compensation, genetic information, harassment, national origin, pregnancy, race/color, religion, retaliation, sex, and sexual harassment.

In a separate but related set of laws, the Genetic Information Nondiscrimination Act of 2008 (GINA) protects individuals against employment discrimination on the basis of genetic information. As described in Section 5.3 of Frees and Huang (2020), GINA also prohibits covered health insurers from discriminating on the basis of genetic information that includes genetic test results, family medical history, and use of genetic services.

The U.S. Department of Health and Human Services Office for Civil Rights enforces federal civil rights laws, including conscience and religious freedom laws. In particular, for individual health insurers, this includes the Patient Protection and Affordable Care Act of 2010 (ACA), the comprehensive health care reform law that addresses health insurance coverage, health care costs, and preventive care. Section 1557 of this act states that individuals shall not be excluded from participation in, be denied the benefits of, or be subjected to discrimination on the grounds of race, color, national origin, sex, age, and disability.

The Fair Housing Act, enacted in 1968, prohibits discrimination in housing-related activities and is now interpreted to include homeowners insurance. Specifically, it is illegal to discriminate because of the race, color, religion, sex, disability, familial status, or national origin of the owner and/or occupants of a dwelling. See, for example, the Department of Housing and Urban Development’s Implementation of the Fair Housing Act’s Discriminatory Effects Standard.

In a similar vein, the Equal Credit Opportunity Act is a federal financial regulation
law enacted in 1974. The act prohibits discrimination on the basis of race, color, religion, national origin, sex, marital status, or age in credit transactions.

Despite these laws and the accompanying regulations, insurance discrimination is largely unregulated at the federal level, leaving the states as the primary regulators of insurer discrimination.

1.1.2 U.S. State Laws and Regulations

Enacted in 1945, the McCarran-Ferguson Act clarified that the states regulate and tax the business of insurance. Efforts of the different states are coordinated by the National Association of Insurance Commissioners (NAIC). This organization is governed by the chief insurance regulators from the 50 states, the District of Columbia and five U.S. territories. The NAIC established standards and best practices that each state may choose to adopt, NAIC (2011). To complement this organization, a U.S. Federal Insurance Office was created in 2010 as an information gatherer to inform the U.S. Congress on insurance matters. The Federal Insurance Office was granted limited authority to enter into covered agreements with other nations on insurance regulatory matters and represents the U.S. with the International Association of Insurance Supervisors.

Despite the structure offered by the NAIC, Avraham, Logue, and Schwarcz (2014) documents a lack of uniformity in state insurance anti-discrimination regulations. Their work demonstrates that affirmative bans of insurer discrimination on the basis of potentially suspect policyholder traits are rare. To illustrate, from their study, “only nine states ban the use of age in auto insurance; only six states ban the use of genetic testing in disability insurance; and only two states ban ... the use of location or zip code in property/casualty insurance.” This lack of uniformity is also observed by Werner and Modlin (2016), who state:

Some states have statutes prohibiting the use of gender in rating insurance while others permit it as a rating variable. As a result, an insurer writing in multiple states may include gender as a rating variable in those states where it is permitted, but not include it in a state that prohibits its use for rating. Some states may allow the use of a rating variable, but may place restrictions on its use. For example, some states allow credit score to be used for rating personal insurance for new business, but do not allow insurers to raise the rates for renewal risks should the insured’s credit worsen (although they may allow companies to reduce rates if the insured’s credit score improves). Some states also prohibit certain variables from use in the rating algorithm but allow their use in underwriting. Underwriting variables may be used to guide risk selection decisions, but could
also guide risk placement decisions.

1.2 European Union

The European Union (EU) is the second largest general insurance marketplace. It comprised about 22% of the 2017 world market (in terms of gross direct premiums, see Table 7 of GIAJ (2019), SwissRe (2018)). This does not include the United Kingdom which represented about 4% in 2017.

1.2.1 EU Directives

The EU is a political and economic union of 27 member countries, not counting the United Kingdom which left in January 2020. The European Commission serves as its executive branch and, among other duties, has the power to propose new laws. For insurance purposes, legislation takes the form of directives, a type of legislative instrument that allows members the freedom to interpret the demands of EU law within their own legislative traditions. For example, Section 5.1 of Frees and Huang (2020), remarked on the 2004 Gender directive with the related court actions. Thus, the requirements set out in the directives have to be interpreted and implemented in each member country by national legislation. In contrast, the U.S. NAIC promulgates model laws and regulations but the states are not required to enact them.

Insurance pricing was essentially deregulated in the EU in 1994 with the introduction of the Third Generation Insurance Directive. Prior to the directive, the European insurance business was mostly embedded in a dense regulatory network. Implementing the 1994 deregulation yielded intensive price competition, primarily lowering prices but in some cases, such as Italy, raising prices, see, for example Hussels, Ward, and Zurbruegg (2005) and FCA (2019).

Equality and respect for human dignity and human rights are among the core values of the EU, reflected in several EU directives targeting discrimination. Initially signed in 1957, Article 10 of the Treaty on the Functioning of the European Union states:

In defining and implementing its policies and activities, the Union shall aim to combat discrimination based on sex, racial or ethnic origin, religion or belief, disability, age or sexual orientation.

However, as summarized in a report was commissioned by the European Commission, Civic Consulting (2010), there is a patchwork of legislative and regulatory measures across the member countries that deal with discrimination. The majority of countries prohibit any form
of discrimination, with no exceptions, on the grounds of racial/ethnic origin, religion/belief and sexual orientation. Treatment of age and disability is less uniform.

1.2.2 EU Member Countries Laws and Regulations

Some member countries regulate conditions that affect the determination of insurance premiums. One example of this is the automobile insurance bonus-malus system in France. Although auto insurance rate levels are not subject to explicit constraints, the premiums are adjusted by a bonus-malus coefficient (set by law) that considers a driver’s past experience. Another set of examples are the restrictions based on non-risk pricing, introduced in Sections 3.3 and 5.3 of Frees and Huang (2020). As described in FCA (2019), Belgium and Italy (as well as non-EU Switzerland) have introduced rules that should limit the use of non-risk based factors in the pricing of insurance.

1.3 China

China is the third largest general insurance marketplace. It comprised about 10% of the 2017 world market (in terms of gross direct premiums, see Table 7 of GIAJ (2019), SwissRe (2018).

As discussed by Chen et al. (2014), there are three levels in the Chinese insurance regulatory system. First, the National People’s Congress and its Standing Committee jointly exercise the power to enact laws in China, including the Insurance Law. Second, the State Council, which is the chief administrative authority of China, develops administrative regulations. Third, the primary regulator of the private insurance market is China Insurance Regulatory Commission (CIRC), which is a functional department of the State Council. There are also industry organizations, including the Insurance Association of China (IAC) and “Intermediary Associations” for insurance intermediaries at the provincial and city levels. The IAC, founded in 2001, is a not-for-profit organization authorized by the CIRC and registered by the National Ministry of Civil Affairs. These organizations formulate industry standards and provide professional industry guidance to constrain unfair activities and strengthen self-discipline.

The Insurance Law was first approved and implemented in 1995 and then modified in 2002 and 2009. In the Insurance Law, the item related to insurance discrimination is Item 114, which states that “Insurance companies should obey the insurance regulations and set insurance premium rates fairly and reasonably, which should not harm the legitimate rights and interests of policyholders, insureds and beneficiaries.” However, this law does not specify how to judge the “fairness” and “reasonableness” (Zhou (2014)).
There are no insurance discrimination prohibitions in the “property insurance regulations” and the “life insurance regulations”. The only discrimination related regulation is in ‘auto insurance rate making procedures and core content (2002)’, which requires insurance rating schedules must be reasonable without any discrimination content. However, it again does not specify nor explain the definition and extent of ‘discrimination’.

The Chinese auto insurance market is comprised of compulsory and voluntary components. The CIRC strictly regulates the pricing of compulsory auto insurance. The only pricing factors are vehicle type and past claim experience. Since 2015, there have been significant regulation changes for voluntary auto insurance. The auto insurance pricing formula depends on a benchmark pure risk premium (determined by the Insurance Association of China), a surcharge rate (management fee, no more than 35%, determined by insurers), and several rate adjustment coefficients, including ones for no claims discount, traffic violation, underwriting, and a “channel.” The benchmark pure risk premium uses only vehicle related information (usage and type) as pricing factors. According to CIRC price guidelines, from 2017 the underwriting coefficient can range within (0.7/0.75/0.8, 1.15/1.25) and the independent channel coefficient within (0.7/0.75, 1.15/1.25) for different provinces. From April 2018, the CIRC approved a pilot experiment in Shaanxi, Guangxi and Qinghai to allow for independent pricing in those provinces. For details of the regulation changes of Chinese auto insurance, please refer to Appendix Section 2.3.

Chinese insurers use life tables published by CIRC for life insurance pricing. For example, the current version is China Life Insurance Mortality Table (2010-2013). The mortality rates in the insurance life tables are age, gender, and product specific. In particular, it has three product categories, including annuities/pension, term life insurance, and whole life insurance.

Like many other insurance markets, age is a commonly used pricing factor in the Chinese life insurance market. Chinese auto insurers also set different rates for different age groups in general insurance practice. For example, age groups below 25 and above 60 are usually treated as high-risk groups with 1.05 rate adjustment coefficient, while the age group between 30 and 40 can be treated as low-risk group with 0.95 risk adjustment coefficient. Gender has also been widely used as a pricing factor in the Chinese insurance market. For example, higher rates applies to males purchasing life insurance and females purchasing annuities. In business auto insurance, many insurers set the adjustment coefficients to be 0.95 for females and 1.00 for males with reference to the basic insurance rating table issued by the government. There are no laws or regulations prohibiting the use of disability, race, or religion related factors in insurance pricing.
1.4 Japan

Japan is the fourth largest general insurance marketplace. It comprised about 5% of the 2017 world market (in terms of gross direct premiums, see Table 7 of GIAJ (2019), SwissRe (2018)).

For additional context, the regulator of the Japanese insurance market is the Financial Services Agency. Insurers operating in Japan have formed the General Insurance Association of Japan whose objective is “to promote sound development and maintain reliability of the general insurance business in Japan, …” Among other activities, this organization actively participates in the International Association of Insurance Supervisors (IAIS) in its standard setting activities. Industry statistics and representative rates are gathered by the General Insurance Rating Organization of Japan. This is a Japanese non-profit, private corporation with a membership comprised of general insurance and reinsurance companies.

The Japanese general insurance market is dominated by personal lines, with about 55% from the auto market, 7% from fire dwelling, and 12% from personal accident insurance, (based on 2017 premium statistics from GIAJ (2019)). The auto market is split into a compulsory liability component, known by the acronym CALI, at about 11% of market share, and the larger voluntary component at about 44% of market share. In terms of insurance pricing, CALI premium rates are calculated by the General Insurance Rating Organization of Japan. In this pricing scheme, automobiles are classified by type, size and use, and are designed to be non-profit. As the name suggests, anyone purchasing an automobile must purchase CALI insurance that pays damages for anyone killed or injured by an insured vehicle.

Voluntary insurance includes third-party liability coverage (bodily injury liability and property damage liability), self-incurred personal accident coverage, and own vehicle damage coverage. With respect to liability for bodily injury, voluntary insurance acts as excess cover for compulsory insurance. Prior to 1998, the auto insurance product was similar across firms. Rates and policies were strictly regulated, and underwriting was limited. In 1998, the marketplace was liberalized to a prior approval system where insurers submit rating plans to the Financial Services Agency who examines the rates on the basis of three principles of premium rates, that they be reasonable, adequate and not unfairly discriminatory (see Section 5.1 of Frees and Huang (2020)). Permissible rating factors include driver’s age, gender, driving history, usage, pattern of use, geography, vehicle type, vehicle safety features, and multi-car ownership. In particular, for age, “Any number of categories allowed, but differentials between the highest and lowest rated groups to be within a range of 300%”. As another example, for gender, “Segmentation allowed, but differentials between male and female to be within a range of 150%” (Source: GIAJ (2017)).
In Japan, mechanisms for mitigating discrimination appear to be different than in other marketplaces perhaps due to the relatively homogeneous culture. Another possible explanation is that industry organizations work diligently with member insurers to mitigate public concerns of potentially awkward situations prior to legislative action. As one example, the General Insurance Association of Japan publishes *Personal Information Protection Guidelines* to encourage member insurers to protect personal information. This is meant to be in accord with the Japanese Protection of Personal Information Act, brought into effect in 2003 and amended in 2017. To ensure consumer protection, during the advance product approval processes for personal lines, the basic principles of reasonableness, adequacy, and not being unfairly discriminatory are considered, along with regular risk category reviews. Algorithms are also required to be explained within the processes.

As another example, the Life Insurance Association of Japan, another industry organization, has said its member firms do not use genetic information to make decisions about coverage, the subject of Section 5.4 of Frees and Huang (2020). Nonetheless, the association acknowledges that people with genetic diseases and private groups supporting them have voiced concerns about discrimination in the absence of laws prohibiting insurers from gaining such data. See Japan Times News (2019).

### 1.5 Australia

Australia is the tenth largest general insurance marketplace. It comprised about 2% of the 2017 world market (in terms of gross direct premiums, see Table 7 of GIAJ (2019), SwissRe (2018)). Australia has anti-discrimination legislation at the federal, state and territory levels. Commonwealth laws and the state/territory laws generally overlap and prohibit the same type of discrimination. Although there are differences in detail, all anti-discrimination legislation reflects the same paradigm for identifying unlawful discrimination Australian Law Reform Commission (2010).

#### 1.5.1 Australian Federal Laws and Regulations

There are four federal acts containing provisions relevant to discrimination in insurance, the Age Discrimination Act 2004 (ADA), the Sex Discrimination Act 1984 (Cth)(SDA), the Racial Discrimination Act 1975 (Cth)(RDA) and the Disability Discrimination Act 1992 (Cth)(DDA). Prohibitions on the use of genetic information in insurance are most likely to

---

1. An unlawful discrimination act or mission must be based on one of the grounds or attributes set out in the legislation, such as sex, race or disability; fall within an area of activity set out in the legislation, such as employment or the provision of goods and services; result in some harm or less favorable treatment, whether by direct or indirect discrimination; and not fall within an exception, exemption or defense.
be brought under the DDA. These acts include general provisions applying to the supply of goods and services, including insurance. As an example, Section 24 of the DDA can be found in the Appendix Section 2.2.

Use of age, disability and gender may be allowed in certain circumstances in that ADA, DDA and SDA all contain exceptions relating to the provision of insurance. Insurance exceptions in the acts contain elements similar to those in Section 46 of the DDA, which applies both to the refusal to offer insurance (Section 46(1)) and to the terms or conditions on which it is offered (Section 46(2)). The details of the statement of Section 46(1) can be found in Appendix Section 2.2. There is no exception for discrimination in insurance based on race, even if one can establish the statistical and actuarial relevance of race information.

Australia does not have a stand-alone religious anti-discrimination law, similar to federal laws that protect against discrimination based on age, sex, race, and disability. However, Australia has a legal obligation to protect the right to religious freedom under a treaty known as the International Covenant on Civil and Political Rights. Domestically, there are a variety of laws that protect religious freedom. In August and December 2019, the Federal Attorney-General released the first and second exposure drafts of the Religious Discrimination Bill 2019 (Cth), which will make it unlawful to discriminate on the ground of religious belief or activity in a range of areas of public life. There is no insurance exception in those drafts.

1.5.2 Australian State Laws and Regulations

Each state and territory in Australia has its own anti-discrimination acts with its own insurance exceptions. In Australian insurance practice, age is commonly used to discriminate, or differentiate, treatment among insureds with few regulatory constraints for the personal lines. For example, auto insurers use the age of the owner/driver of the car as a pricing factor. Life insurers consider the age of the policyholder as a pricing factor. They may also have age constraints to access specific insurance contracts. For example, it is common to require ages 16 - 65 in order to apply for the life cover and to require ages 16 - 55 to apply for critical illness cover or permanently unable to work cover.

Gender and disability are also commonly used pricing factors for the personal lines. For example, auto insurers use the gender and disability of owners/drivers of the car as pricing factors. Life insurers apply the gender and state of health of the policyholder as pricing factors.

In the Australian auto market, Compulsory Third Party (CTP) insurance (also called the greenslip) is required in all states and territories of Australia. The CTP insurance provides compensation for people injured or killed when the insured vehicle is involved in an accident. The CTP insurance is highly regulated, as it can be regarded as a social safety net or social good, so social considerations are more important in this case, as introduced in Section 2.1 of Frees and Huang (2020). The pricing factors allowed to be used in CTP insurance varies across different states. For example, the Australian Capital Territory’s CTP insurance scheme is a “community rated” scheme, with all motorists for each vehicle class pay the same amount regardless of their individual risk profile. The Victorian CTP insurance scheme allows the use of three factors to determine the premium, which are the vehicle classification (vehicle type and use), postcode, and eligibility for a pensioner discount. The New South Wales’ CTP insurance is the least regulated compared with the other states and territories. It allows the use of more factors for pricing, including for example geographic region, type of vehicle, age of vehicle, distance traveled and Vehicle performance and else.

Voluntary Comprehensive Car Insurance and Third Party Insurance is also offered in the Australian auto market. Comprehensive insurance cover damage to the insured vehicle, damage to other vehicles, damage to or loss of property and theft of the insured vehicle. Third party property insurance only covers damage to other vehicles involved in an accident. Unlike CTP insurance, these voluntary coverages are less regulated, as they are not regarded as a social good and economic considerations dominate more in this case. Insurers can set prices using a range of rating factors for risk classifications. Historically, pricing models used by insurers in Australia have been less advanced. However, most large insurers now have highly sophisticated pricing models, see FCA (2019).
Table 1: Logistic Regression Model of Being Female Summary

|                              | Estimate | Std. Error | z value | Pr(>|z|) |
|------------------------------|----------|------------|---------|---------|
| (Intercept)                  | -0.409   | 0.162      | -2.526  | 0.012   |
| VehBody.Hatchback            | 1.707    | 0.128      | 13.334  | 0.000   |
| VehBody.Sedan                | 1.354    | 0.119      | 11.334  | 0.000   |
| ‘VehBody.Station wagon’      | 0.950    | 0.122      | 7.820   | 0.000   |
| ‘VehBody.working people’     | 0.224    | 0.077      | 2.911   | 0.004   |
| VehBody.Minibus              | 1.601    | 0.339      | 4.721   | 0.000   |
| ‘VehBody.oldest people’      | -0.478   | 0.117      | -4.098  | 0.000   |
| VehBody.Hardtop              | 0.794    | 0.205      | 3.876   | 0.000   |
| VehBody.Coupe                | 0.863    | 0.266      | 3.250   | 0.001   |
| ‘VehAge.oldest cars’         | -0.466   | 0.102      | -4.559  | 0.000   |
| VehValue                     | -0.155   | 0.041      | -3.770  | 0.000   |
| ‘DrivAge.old people’         | -0.213   | 0.094      | -2.259  | 0.024   |
| ‘VehAge.old cars’            | -0.186   | 0.082      | -2.262  | 0.024   |
| VehBodyConvertible          | 2.240    | 1.268      | 1.767   | 0.077   |

2 Appendices

2.1 Appendix: A Proxy for Being Female

This appendix shows the results of the use of a classical automatic technique, stepwise regression, to develop a desirable proxy for the probability of being female. The R code is in Appendix Section 2.4. In addition to the main variables used for predicting claim amounts, VehValue and DrivAge, it also uses two other variables from the datafile:

- VehAge - The vehicle age group, and
- VehBody - The vehicle body group.

FemLogit1Sum <- summary(FemLogit1)
kable_styling(knitr::kable(coefficients(FemLogit1Sum),digits=3,
caption="Logistic Regression Model of Being Female Summary",
vlime = "", linesep = c("", "", "\addlinespace"), align = "rrrr"), font_size=10)

plot(density(FemLogit1$fitted.values), xlab = "Fitted Probability",
main = "Estimated Probability of Being Female")
2.2 Appendix: Australian Regulations

Section 24 of the DDA has the following provisions relating to disability provision:

(1) It is unlawful for a person who, whether for payment or not, provides goods or services, or makes facilities available, to discriminate against another person on the ground of the other person’s disability or a disability of any of that other person’s associates:

(a) by refusing to provide the other person with those goods or services or to make those facilities available to the other person; or
(b) in the terms or conditions on which the first-mentioned person provides the other person with those goods or services or makes those facilities available to the other person; or
(c) in the manner in which the first-mentioned person provides the other person with those goods or services or makes those facilities available to the other person.

(2) This section does not render it unlawful to discriminate against a person on the ground of the person’s disability if the provision of the goods or services, or making facilities available, would impose unjustifiable hardship on the person who provides the goods or services or makes the facilities available.

Section 46 (1) of the DDA has the following provisions relating to insurance exemptions:

(1) This Part does not render it unlawful for a person to discriminate against another person, on the ground of the other person’s disability, by refusing to offer the other person:

(a) an annuity; or
(b) a life insurance policy; or
(c) a policy of insurance against accident or any other policy of insurance; or
(d) membership of a superannuation or provident fund; or
(e) membership of a superannuation or provident scheme;
if:
(f) the discrimination:
   (i) is based upon actuarial or statistical data on which it is reasonable for the first
      mentioned person to rely; and
   (ii) is reasonable having regard to the matter of the data and other relevant factors;
    or
(g) in a case where no such actuarial or statistical data is available and cannot rea-
    sonably be obtained—the discrimination is reasonable having regard to any other
    relevant factors.

Data disclosure requirements for the exception of insurance based on sex discrimination are listed
below in SDA:

if the client gives the insurer a written request for access to the data—either:
(i) the insurer gives the client a document containing the data; or
(ii) the insurer:
   (A) makes a document containing the data available for inspection by the client at such
       time or times, and at such place or places, as are reasonable; and
   (B) if the client inspects the document—allows the client to make a copy of, or take
       extracts from, the document.

2.3 Appendix: Chinese Regulations

We summarize the history of the regulation changes in Chinese voluntary auto insurance market in
the table below.

Table 2: The history of regulation changes in Chinese voluntary auto insurance market

<table>
<thead>
<tr>
<th>Time</th>
<th>Regulation</th>
</tr>
</thead>
</table>
| 2001/10  | First regulation change after becoming a member of WTO. A pilot experiment in
          | Guangzhou to give the pricing rights to insurers, who use factors related to both
          | the vehicle (type, age, etc.) and driver (age, gender, driving age, etc.) for pricing purposes. |
| 2003     | New pricing regulation for the whole country to give the pricing rights to insurers |
| 2006/3   | To stop the market chaos, the pricing was again regulated. No more than 30% discount |
          | of the benchmark pure risk premium can be applied.                                 |
| 2015-    | The CIRC makes marketization of the auto insurance market as the objective again and |
| 2018     | gradually relax the the regulation by increasing the pricing bounds.              |
2.4 R Code

This section provides R Code for the Section 6.3 of Frees and Huang (2020) empirical example and the Appendix Section 2.1.

Read In the Data

```r
#install.packages("CASdatasets", repos = "http://cas.uqam.ca/pub/R/", type="source")
library(CASdatasets)
data(ausprivauto0405)
ausprivauto0405$Female <- 1*(ausprivauto0405$Gender=="Female")
ausprivauto0405$DrivAge = relevel(ausprivauto0405$DrivAge, ref="youngest people")
ClaimsData <- subset(ausprivauto0405, ClaimAmount>0)
```

Fit Gamma Regression Model

```r
AmtGamma1 = glm(ClaimAmount ~ VehValue+DrivAge+Female
, family=Gamma(link=log), data= ClaimsData)
sum.AmtGamma1 <- summary(AmtGamma1)
kable_styling(knitr::kable(coefficients(sum.AmtGamma1),digits=3,
caption="Gamma Regression Model 1 Summary",align = "ccccccc|"),
font_size=10)
```

Plot Distribution of Fits

```r
par(mfrow = c(1,2))
plot(density(AmtGamma1$fitted.values, bw=80), xlab = "Fitted Value", main = "")
boxplot(AmtGamma1$fitted.values ~ ClaimsData$Female, ylab="Fitted Value", xlab="Female")
```

Develop the Proxy for Being Female

```r
#Proxy For Female
#install.packages("dummies")
library("dummies")
ClaimsData1 <- subset(ClaimsData, select =
- c(ClaimOcc, ClaimNb, Gender, Exposure, ClaimAmount))
ClaimsData2<- dummy.data.frame(ClaimsData1, sep = ".")
big.mod = glm(Female ~ .
, family=binomial(link=logit),data= ClaimsData2)
base.mod <- glm(Female ~ 1
, family=binomial(link=logit),data= ClaimsData2)
# perform step-wise algorithm
stepMod <- step(base.mod, scope = list(lower = base.mod, upper = big.mod),
direction = "both", trace = 0, steps = 1000)
shortlistedVars <- names(unlist(stepMod[[1]]))
shortlistedVars <- shortlistedVars[!shortlistedVars %in% "(Intercept)"
]vars <- gsub("\\n","",shortlistedVars)
ClaimsData3<- subset(ClaimsData2, select = c("Female", vars))
FemLogit1 = glm(Female ~ .
, family=binomial(link=logit), data= ClaimsData3)
```

Annotated Bibliography

———, Kyle D Logue, and Daniel Schwarcz (2014), “Understanding insurance antidiscrimination law,” Southern California Law Review, 87, 195–274 This paper describes fairness and efficiency arguments for introducing insurer prohibitions on underwriting. It uses these arguments to describe U.S. state approaches for nine potentially sensitive characteristics: race, national origin, religion, gender, sexual orientation, age, credit score, zip (postal) code, genetics. This description is for each of five lines of business: auto, disability, health, life, and property/casualty. The paper documents how U.S. state insurance antidiscrimination laws vary a great deal: in substance and in the intensity of regulation, across lines of insurance, across policyholder characteristics, and across states. It also remarks that a surprising number of jurisdictions do not have any laws restricting insurers' ability to discriminate on the basis of race, national origin, or religion, commonly referred to as the "big three" in American law.

Baker, Tom (2002), “Risk, insurance, and the social construction of responsibility,” Embracing Risk: The Changing Culture of Insurance and Responsibility, 33–51 Reaching out to insurance institutions for protection cedes responsibility to them. Risk not only creates responsibility, but also socializes that responsibility. Baker argues that insurance is a form of social responsibility and that insurance institutions shape responsibility in five distinct senses: accountability, trustworthiness, causation, freedom, and solidarity.

Borselli, Angelo (2011), “Insurance rates regulation in comparison with open competition,” Connecticut Insurance Law Journal, 18, 109–68 The main thesis of this paper is to argue for rate deregulation in the U.S. as a superior alternative to the current regulation model. An extensive historical analysis is provided to support this thesis, as well as some empirical facts about the U.S. market, and a comparison of the European experience.
with insurance deregulation. To supplement the analysis, the paper includes a description of rate filing methods being used at the state level.

Cather, David A (2018), “Cream skimming: Innovations in insurance risk classification and adverse selection,” Risk Management and Insurance Review, 21 (2), 335–66 As stated in the title, this paper documents how advances in classification can lead to cream skimming, a type of adverse selection, against insurers that are slow to adopt such pricing innovations. This is done by providing an overview of the switching literature in economics/marketing and by describing two auto insurance case studies, one on the adoption of credit-based insurance scores and one on the introduction of usage-based insurance programs such as telematics.

Frezal, Sylvestre and Laurence Barry (2019), “Fairness in uncertainty: Some limits and misinterpretations of actuarial fairness,” *Journal of Business Ethics*, 1–10. This article provides a historical overview of the concept of actuarial fairness in an insurance context. It distinguishes two viewpoints of actuarial fairness: (1) as a solidarity among a group of insureds pooling their uncertain results and (2) as a fair contract between an insured and an insurance company.

Kleinberg, Jon, Sendhil Mullainathan, and Manish Raghavan (2016), “Inherent trade-offs in the fair determination of risk scores,” arXiv preprint arXiv:1609.05807. This paper formulates three core fairness conditions in algorithmic classification that correspond to notions of fairness: calibration within groups, balance for the negative class, and balance for the positive class. They find that except in highly constrained cases, there is no method that can satisfy the three conditions simultaneously.

Lehtonen, Turo-Kimmo and Jyri Liukko (2011), “The forms and limits of insurance solidarity,” *Journal of Business Ethics*, 103 (1), 33–44 When taking out an insurance, one participates in a risk pool in which each member is reciprocally responsible for others’ risks; this is insurance solidarity. This paper describes relationships among insurance, solidarity, and welfare. It further seeks to clarify the role of solidarity in both private and social insurance.

Lindholm, Mathias, Ronald Richman, Andreas Tsanakas, and Mario V Wuthrich (2020), “Discrimination-free insurance pricing.” Available at SSRN

This paper considers the same discrimination-free pricing formula as that in Pope and (2011). However, they provide a rigorous probabilistic justification for the pricing procedure. They also justify the pricing framework using casual inference. To overcome the bias caused by the discrimination-free pricing formula, they propose bias correction strategies at the portfolio level. Empirical illustrations using both GLM and neural networks demonstrate how to apply the proposed methods for insurance pricing.

Maysami, Ramin Cooper and W Jean Kwon (1999), “An analysis of islamic takaful insurance.” *Journal of Insurance Regulation*, 18 (1) Takafal means shared responsibility; takaful insurance is a form of insurance that is permitted under Islamic guidelines. This paper describes Islamic socioeconomic principles applied to insurance, including concepts of uncertainty, interest, and investment arrangements. It further describes takaful life insurance, non-life insurance and reinsurance.

Miller, Michael J (2009), “Disparate impact and unfairly discriminatory insurance rates,” in *Casualty Actuarial Society E-Forum, Winter 2009*, 276 In the U.S., "unfairly discriminatory insurance rates" are based on the costs of supplying insurance. This paper emphasizes conflicts that arise between cost-based rate practices and other rating practices that accommodate potential disparate impact effects. To motivate the discussion, it provides historical overviews of (U.S.) rate regulation and standards as well as (U.S.) laws and court decisions regarding disparate impact.

Pope, Devin G and Justin R Sydnor (2011), “Implementing anti-discrimination policies in statistical profiling models,” *American Economic Journal: Economic Policy*, 3 (3), 206–31 This paper proposes an anti-discrimination pricing method, which first estimates the full model to obtain the coefficient estimates, and then averages across the potential protected (SUP) values in the population. This approach can eliminate proxy effects while maintaining predictive accuracy relative to an approach that removing the contentious variables outright.

Prince, Anya and Daniel Schwarcz (2020), “Proxy discrimination in the age of artificial intelligence and big data,” *Iowa Law Review*. Accessed https://papers.ssrn.com/sol3/papers.cfm?abstract_id=3347959. Retrieved on Dec 21, 2019. As learning algorithms become smarter and big data gets bigger, proxy discrimination represents an increasing challenge to anti-discrimination regimes. This paper describes how these advances can undermine these regime outcomes that include (1) promoting social risk-sharing, (2) preventing the chilling of socially-valuable behavior, (3) limiting the effects of past discrimination, and (4) protecting non-conforming members of groups from being saddled with their group’s characteristics.

Schmeiser, Hato, Tina Störmér, and Joël Wagner (2014), “Unisex insurance pricing: Consumers’ perception and market implications,” *The Geneva Papers*, 39, 322–350. Motivated by the European Court of Justice 2011 ruling that forbade sex discrimination in insurance, this paper reports on a survey conducted of customers concerning several price differentiation criteria, including sex. The survey asked about four key insurance products, motor, annuity, life and health, and spanned customers in five European Union countries, the United Kingdom, Germany, France, Italy, and Switzerland. The study showed that consumers accepted differentiation by price criteria, although there were substantial differences by line of business and by country.

INTRODUCTION

Nyce [1] provides an excellent introduction to government insurance including the five main reasons for government insurance, which are summarized in this study note.

Both the federal and state governments are involved in insurance as regulators of insurance companies and as insurers. As insurers, they participate in a number of insurance programs either as the sole insurer, in partnership with insurance companies or in competition with insurance companies. Several major programs that are discussed elsewhere in the syllabus include the National Flood Insurance Program, Social Security, Guaranty Funds, FAIR plans, TRIA, and various state Auto Plans. In this study note, we will discuss state and federal involvement in Workers Compensation Insurance, Crop Insurance, and Unemployment Insurance.

Is government participation in insurance necessary? According to Greene and Weining, there are several reasons for government participation in insurance:

- Filling insurance needs unmet by private insurance
- Compulsory purchase of insurance
- Convenience
- Greater efficiency
- Social purposes

Filling Insurance Needs Unmet by Private Insurance

According to Nyce [1] and Greene [2], one justification for government participation in insurance is the residual market philosophy, with governments offering insurance in markets unserved by private insurance; either because of unavailability or affordability. One implication of the residual market philosophy is that government requirements for insurability are different from private insurers’ requirements. A government may step into situations in which private insurers do not because the government has the financial capacity to subsidize losses, either by directly taxing taxpayers for the insurance program even those who do not benefit from the program, or indirectly by charging less than the actuarial cost of providing insurance coverage for the exposure and making up the difference through government-provided funds (crop / flood). There are strong
arguments, both pro and con, as to whether a government should provide this type of subsidy.

Begun in 1968, the Federal Crime Insurance Program was intended to provide coverage for homeowners and small businesses located in neighborhoods with high crime rates, primarily because private insurance for burglary or robbery was not available at affordable rates for these risks. With proper loss prevention methods, this insurance was available from the private market at rates less than the government rates and the Federal Crime Insurance Program expired in 1995.

Crop insurance and Flood insurance are available and affordable only because of subsidies from the federal government.

*Compulsory Purchase of Insurance*

Government may require individuals or businesses to obtain insurance to meet social responsibilities. A driver who causes an automobile accident is responsible for repairing the damage or injury caused by the accident. Many people would not have the financial resources to meet this obligation without insurance protection. An employer is deemed responsible for injury to an employee regardless of fault. Again, without insurance protection an employer may not be able to meet this obligation. Without a compulsory insurance requirement, some persons who have suffered injury or loss may not have the costs of repairing the damage to their property or their medical costs covered by the person responsible for these costs.

Since purchase of insurance such as workers compensation or automobile insurance may be compulsory, some state legislatures felt obliged to offer the insurance to individuals who could not find a private market [2]. The workers compensation state funds established in several states and the Maryland Automobile Insurance Fund are examples of this philosophy. Another reason why some federal and state legislators believe that government should provide compulsory insurance is that private companies should make only limited profits, given the government guaranteed market. A government program would operate as a not-for-profit entity and the cost of the compulsory insurance would be lower than if offered by a for-profit insurer. In other non-insurance government mandated programs such as highway construction contracts, private organizations often service the program. Within a purely competitive market excessive profits cannot persist in the long run. Private insurance seems to work for most states in supplying the vast majority of the public with compulsory insurance such as workers compensation and auto insurance.

While workers compensation insurance is administered by a monopolistic state fund in a few states, most states have private companies that offer workers compensation insurance, sometimes in competition with state-run funds that will provide coverage to anyone who applies for coverage to the fund, sometimes referred to as “take all comers.” For those states without a state fund, and some with a state fund, there is usually some
other form of residual market that provides coverage to those who are unable to find the required coverage with a private insurer.

For compulsory auto insurance, government insurance is normally not the answer; so provisions are in place to make auto insurance available for those unable to buy insurance on the open market. Sometimes these alternate sources also provide the coverage at costs below the actuarial cost of providing the coverage. In these situations, insurers, other insureds or taxpayers subsidize part of the cost of the coverage for high risk drivers. Hamilton and Ferguson [3] discuss these provisions, which include assigned risk plans, reinsurance facilities, and joint underwriting associations depending on the state. Maryland has the only state-owned auto insurance company.

Convenience

Some government insurance programs are established because it appears to be easier for the government to set up a program quickly as a legislature can appropriate funding for the new program, whereas the private market may take longer to find the necessary funding [3]. A government program may also be already set up to provide certain types of services needed by the insurance program. These services include loss mitigation development and funding, as the Florida legislature did when establishing the Florida Hurricane Catastrophe Fund.

Using government insurance programs only for convenience may not be justified if the private market is willing and able to provide a reasonable market.

Greater Efficiency

One argument in favor of government insurance is that there is greater efficiency than in the private market [2]. Some government insurance programs may be established because of the belief that government can provide the service at a lower cost than the private market. However, the costs of providing insurance, including the costs of keeping records, providing consumer education, issuing policies and paying claims, exist even in government insurance programs. Services such as explaining coverages, keeping records, and handling claims questions are still provided by customer service representatives (who must be compensated). The cost savings claimed for government insurance programs might be overstated because other government departments may perform services on behalf of the government insurance entity that are usually performed by insurance companies, including appraising property, administering claims, or making investments.

Social Purposes

The use of government insurance to achieve social purposes may be the main reason for government insurance programs [3]. Some feel that these social purposes can only be fully achieved within government-owned insurance programs. For example, rehabilitation and vocational training of injured workers are important goals of a workers compensation
system and requirements for loss mitigation in catastrophe insurance plans may be more easily accomplished under government insurance programs. Can private insurance programs accomplish the same goals? If Social Security benefits were made available through a welfare program for the truly needy elderly and disabled while pension plans, 401(k)s, life insurance and disability insurance were to be used to fill the needs of others, would adequate protection for retirement and the disabled be available? If building codes and zoning requirements could be altered to prevent construction in flood-prone areas would private insurers be willing to provide flood coverage? In this scenario, government flood insurance would still be needed for existing buildings in the flood zones, but the need for government flood insurance on new construction would be reduced.

Level of Government

The government (either state or federal) can be involved in three levels as either exclusive insurer, partner with private insurers or as a competitor to private insurers. As an exclusive insurer the government functions as a primary insurer by collecting premiums, providing coverage and paying all claims and expenses. An example of this at the federal level is Social Security and at the state level with some state government-run workers compensation programs.

In partnership with private insurers the government offers reinsurance coverage on specific loss exposures for which the private insurer may retain only a portion of the loss. Examples of this at the federal level are National Flood insurance program, Terrorism Risk Insurance Program and Federal Crop insurance. On the state level this includes several programs to address residual markets where the insured cannot find coverage on the open market. Examples of this are Fair Access to Insurance Requirements (FAIR) plan, Workers Compensation, Windstorm plans and Residual Auto Plans.

In some cases the states operate in direct competition to private insurers such as in the Workers Compensation market in some states.

Detail of the various government insurance plans are provided in this document or in other readings on the Syllabus.

Evaluation of Government Insurance Programs

How well have the federal and state governments performed in providing insurance? According to Greene [2] the questions to be asked are:

- Is the provision of the insurance by the government necessary or does it achieve a social purpose that cannot be provided by private insurance?
- Is it insurance or a social welfare program? Social welfare is designed to provide benefits to qualified people based on demonstrable need for assistance without any payment or contribution by those receiving assistance. These benefits are usually
financed by general tax resources. The public welfare programs are an example of social welfare.

- Is the program efficient, is it accepted by the public?

Based on experience in 2004, 2005 and 2012 how is the Federal Flood Insurance Program performing? The rates don’t seem to be actuarially sound; insurance is usually only purchased if required by law or mortgage companies; people who do not buy flood insurance seem to be getting federal disaster assistance. With appropriate rates, enforceable building codes, up-to-date flood maps, and available reinsurance could private insurance companies provide flood insurance?

In the following sections, we will discuss several government insurance programs, how they work, their origin and purpose, and their effectiveness.

### CROP INSURANCE

To help farmers recover from the Great Depression and the Dust Bowl, in 1938 the federal government created the Federal Crop Insurance Corporation (FCIC), a wholly owned corporation of the U.S. Department of Agriculture (USDA), to oversee the newly created federal crop insurance program. The initial program, intended to provide farmers protection against low yields, was limited to a few major crops (wheat and corn) in the main producing areas [4] and was not successful due to high costs and low participation by farmers [5]. In 1980, Congress passed legislation that expanded the types of crops covered and the regions of the country in which the federal crop insurance was available. To encourage participation the 1980 Federal Crop Insurance Act also authorized a subsidy of the crop insurance premium. According to the Congressional Research Service, in 2014 farmers paid about 38 percent of the policy premium [6].

In the late 1980's and early 1990's, droughts, and wet and cool growing seasons resulted in Congress passing several disaster bills to assist farmers in recovering from these disasters. These disaster bills were still costly and competed with the insurance program, so in 1994, Congress made participation in the crop insurance program mandatory for farmers to be eligible for payments under price support programs, certain loans and other benefits. In addition, catastrophic coverage became available and the premium for this coverage was completely subsidized.

In 1994, the mandatory participation requirement was repealed, but farmers who accepted other types of benefits were required to purchase crop insurance. Participation in the crop insurance program increased significantly.

Multiple Peril Crop Insurance policies are a public-private partnership. Private insurers market and write crop insurance policies, which generally indemnify farmers if yields fall below a given baseline due to natural causes (drought, heat, cold, fire, wind, or flood). Some policies also provide protection if prices fall below a given level. The RMA sets
the rates for these policies and determines which crops can be insured in different parts of the country. The private insurer services the policies including adjusting and settling any claims resulting from the policies. The RMA acts as a reinsurer, reimbursing the participating insurers for losses in return for a portion of the premium. In addition, the federal government reimburses the private insurance companies for their operating and administrative costs. The premiums paid by farmers are subsidized by the federal government to reduce the cost to farmers and encourage farmers to participate in the program.

A farmer must elect to purchase multi-peril coverage prior to planting. The crop insurance subsidies may encourage farmers to purchase more coverage than they might if they paid the full price. A higher participation in the program provides better protection to farmers and may reduce requests for disaster assistance, but it also increases costs to taxpayers.

The Federal crop insurance program differs from most private insurance programs in that an insurer who participates in the Federal program must sell the coverage to any farmer at the rate set by the Federal government. Because the insurer cannot impose its own underwriting standards, judgment or desired rate level regardless of the risk, the risk sharing agreement between the federal government and insurance companies allows an insurer to transfer some liability associated with riskier policies to the government and retain profits or losses on less risky policies.

Some private insurers offer crop-hail insurance which is not part of the federal program. Unlike the multi-peril coverage, a crop-hail policy may be purchased at any time during the growing season. Many farmers purchase this coverage because hail can totally destroy a planted field.

Crop insurance is not mandatory. Farmers may choose whether to buy it, and for which crops. However, the RMA requires that if a farmer chooses to insure a particular field, he or she must insure all of his or her fields growing the same crop in the same county. This alleviates problems of adverse selection, since otherwise farmers would insure only their most loss-prone locations and the program would bear a higher loss ratio. In addition, farmers who choose to forego crop insurance are not eligible for payments for crop loss from federal disaster relief programs.

Supporters of federally backed crop insurance argue that it is necessary to bring stability to a very volatile but important sector of the American economy. Private crop insurance would definitely be more expensive (if the subsidy were removed), and might be substantially more expensive or even unavailable due to the risk of catastrophic losses over a large geographic region. Opponents have charged that crop insurance subsidies encourage agricultural over-production and encourage farming in marginal and disaster-prone areas, which harms the environment and increases general disaster relief costs.
WORKERS COMPENSATION INSURANCE

With the advent of the industrial revolution, new technology and machinery resulted in more industrial accidents. The only recourse an injured worker had was to sue their employer - a long, expensive process with an uncertain outcome. Workers compensation benefits evolved as a means by which employees injured on the job would be certain to have their injuries adequately taken care of by their employer without having to sue. Employers, as well as employees, benefited from the new system as the employer also exchanged an uncertain, potentially large payment, for a certain guaranteed benefit system.

Governments, both state and federal, participate in workers compensation insurance programs in a variety of ways. In some states, workers compensation insurance is only available through private insurance companies, while in other states it is only available from a state fund (an entity established by law to provide workers compensation insurance.) In some states, a state fund may compete with private insurers. In all states, government and private insurers cooperate in providing workers compensation insurance as the benefits are defined by law, either state or federal, and unless there is an exclusive state fund, private insurers provide the insurance coverage.

Workers compensation programs covering most employees are enacted and administered at the state level in all fifty states, the District of Columbia and the five U.S. territories. Federal government employees and certain categories of workers, such as longshoremen or railroad workers, are covered by federal workers compensation programs.

A) Federal Workers Compensation Programs

Various federal programs compensate certain categories of workers for disabilities caused on the job and provide benefits to dependents of workers who die of work-related causes. The federal government works to ensure these programs perform well under the U.S. Office of Management and Budget and Federal Agencies. The following are some major federal programs:

1) The Federal Employee Compensation Act (FECA) provides compensation benefits to non-military, federal employees for disability due to personal injury sustained while in the performance of duty and for employment-related disease. It is administered by the Office of Workers’ Compensation Programs (OWCP) in the U.S. Department of Labor.

The Act is the exclusive remedy for federal civilian employees who suffer occupational injury or illness. There is some claimant overlap with other federal programs; however, regulations generally bar the receipt of dual benefits for the same injury/illness and mandate the reduction in benefits to offset other sources of compensation.

The program’s purpose is to return individuals to work while containing the costs of the system. Designed as a non-adversarial system (i.e., no judicial review and limited
employer ability to contest claims) the program limits administrative and litigation costs, which may account for a substantial share of payout in some systems.

2) The Longshore and Harbor Workers’ Compensation Act of 1927 requires employers to provide workers compensation protection for longshore, harbor, and other maritime workers who are injured or suffer occupational diseases while working on or near navigable water in the United States. These benefits are provided by employers by either procuring insurance coverage from private insurers or by qualifying to self-insure. In some special circumstances, such as second injuries or default in payment of claims by insurers or employers, benefits are paid by a special fund administered by the Department of Labor Employment Standards Administration, Division of Longshore and Harbor Workers’ Compensation (DLHWC). The DLHWC is responsible for adjudicating disputed claims and ensuring that employers and carriers pay benefits.

The Act was created to provide workers’ compensation coverage for categories of workers who were not seamen and were injured while working on or near navigable water in the United States and for which no state act coverage applied. Since the enactment of the Act, there have been questions regarding when coverage under the Act ends and state act coverage begins, particularly when the injury occurs “near” navigable water. In 1984 the scope of the program was amended in an attempt to clarify the extent to which shoreside coverage applied. However, about 40 states allow concurrent receipt of state and longshore benefits. The Act provides for the offset of compensation paid to individuals under any other workers compensation law for the same disability or death. The possibility of an injured worker pursuing either longshore benefits or state act benefits is an issue that employers need to be aware of so that they have adequate insurance protection for their exposure.

3) The Black Lung Benefits Act (BLBA) provides wage-replacement and medical benefits to coal miners who are totally disabled due to pneumoconiosis (black lung disease) and to eligible survivors.

The program was established in 1969 out of concern that black lung victims were not receiving adequate recompense from state workers compensation systems. States have sometimes been slow to recognize chronic occupational diseases such as black lung as compensable injuries. Coal miners frequently change employment, which made it difficult to assign responsibility for a chronic disease to a particular employer. In addition, the BLBA acts as a form of disability insurance, providing compensation to survivors and dependents over and above medical care and loss of earnings. Black lung victims do remain eligible for ordinary workers compensation benefits, but if an individual receives both state and federal benefits, the federal benefit is reduced by the full amount of the state benefit.

Federal benefits are paid by the Black Lung Trust Fund which is financed by coal mine operators through a federal excise tax. In years when payouts exceed revenues, the fund borrows from general government revenue. These deficits are intended to eventually be
paid back with interest. In 2008, however, the Trust Fund deficit had grown so large that Congress made a one-time appropriation to reduce the deficit out of general funds. The hope as of 2016 is that the deficit will eventually be paid down without further excise tax increases or appropriations from general revenue.

B) State Workers Compensation Programs

The state government can act as a partner with private insurers, a competitor of private insurers, or an exclusive insurer.

Partnership with Private Insurers

State programs vary concerning who is allowed to provide insurance, which injuries or illnesses are compensable, and the level of benefits. State laws prescribe workers compensation benefits, but these laws assign to employers the responsibility for providing benefits. Employers can obtain workers compensation coverage to provide benefits to their employees by purchasing insurance from a private carrier or a state workers compensation fund, depending upon the options available in their state. They can also use self-insurance in almost every state if they demonstrate the financial capacity to do so by meeting certain requirements.

Private insurers are allowed to sell workers compensation insurance in all but a few states and territories that have exclusive state funds. Where private insurers may sell workers compensation, a public-private partnership exists since the benefits are established by state law, but insuring those benefits is the role of private insurers.

State Funds

With enactment of state workers compensation laws, the need for workers compensation insurance created its own set of problems, while solving others. Employers feared they would be forced out of business if refused coverage by insurance companies. They were also fearful that insurance carriers might impose excessive premium rates that would be a financial burden. High premium rates could negatively affect a state’s economy and ultimately limit opportunities for employment. Another fear was that because the mandatory nature of the coverage reduces elasticity of demand, insurance rates might soar, enabling insurers to reap unfair profits. Some state legislators addressed these concerns by establishing state workers compensation insurance funds to provide a stable source of affordable insurance coverage.

Washington was the first state to adopt the state fund approach in 1911 and by the end of 1916, thirteen states had established state funds. As of 2016, a total of twenty-three states have state funds that provide workers compensation insurance [7].
In general, state funds are established by an act of the state legislature, have at least part of their board appointed by the governor, are usually exempt from federal taxes, and typically serve as the insurer of last resort – that is, they do not deny insurance coverage to employers who have difficulty purchasing it privately.

Among the twenty-three states that have state workers compensation funds, four have exclusive state funds and nineteen have competitive state funds. The four states with exclusive funds are North Dakota, Ohio, Washington and Wyoming. The South Carolina state fund is a hybrid; it is an exclusive insurer for state employees and is available to cities and counties to insure their employees, but it does not insure private employers.

**Competitive State Funds**

In states with competitive state funds [8], state funds sell workers compensation insurance, at least theoretically, in competition with private insurers in insuring and administrating the workers compensation laws. In some states, Oklahoma is one example, the state fund is not permitted to refuse coverage to an employer, no matter how undesirable the risk, so long as past and current premiums are paid. In this regard they are referred to as “insurers of last resort”. In other states such as Oregon, the state fund does not operate as the insurer of last resort. The mission of the state fund is set out in the Oregon statute that authorizes the existence of the state fund. This mission is to “make insurance available to as many Oregon employers as inexpensively as may be consistent” with protecting the integrity of the Industrial Accident Fund and sound principle of insurance [9].

**Exclusive State Funds**

In states with exclusive state funds, private insurers are not permitted to provide workers compensation insurance and state funds enjoy the exclusive right to sell workers compensation insurance. All employers are required to procure their workers compensation insurance from the state fund, or, in some jurisdictions, an employer may also self-insure.

**Residual Markets**

In states without a state fund, or with a state fund that does not serve as an “insurer of last resort”, it will sometimes happen that an applicant for workers compensation insurance is unable to obtain coverage. Private carriers are limited by regulation in the rates that they can charge. If they believe that the maximum rate will be inadequate for a particular insured, they simply decline to write the policy. This may be because the prospective insured has an inherently hazardous business model, or poor safety practices, or a poor or inadequate loss record.
If states took no action on behalf of such applicants, the applicants would have little choice but to go out of business. This would increase unemployment and impair tax revenues. As a result states without state funds have set up residual market mechanisms to act as insurers of last resort.

The details of this mechanism vary from state to state. Applicants generally enter the residual market after being declined by at least two private carriers. In some states such applicants are assigned to carriers based on their workers compensation market share, with the carriers writing policies and collecting premium and paying claims just as if they were serving the applicants voluntarily.

In other states, carriers reinsure undesirable applicants via a reinsurance pool, and profits or losses from the pool are shared among carriers in proportion to market share. In still other states, the state authorizes a Joint Underwriting Association to serve the residual market, and with carriers sharing on a pro-rata basis profit or loss. Note that these residual market mechanisms closely parallel the automobile liability residual market mechanisms described by Cook [10].

The market share within the residual market varies from state to state and year to year, depending on filed rate adequacy and the risk appetites of insurers. In 2014 the aggregate residual market share was about 8% within the states for which the National Council on Compensation Insurance (NCCI) collects data. The combined ratio for residual market business, over the last several years, has been running between 105% and 115% [11]. As one would expect, residual market business is generally written at a loss despite generally higher rate levels for residual market risks. This results in a higher combined ratio for workers compensation insurers, either directly as residual risks are assigned to carriers, or indirectly as reinsurance or JUA losses are pro-rated. The voluntary market effectively subsidizes the higher-risk residual market, despite higher rate levels for residual market risks.

C) Evaluation of Workers Compensation Insurance

Private carriers remain the largest source of workers compensation benefits. In 2013, they accounted for 56% of benefits paid in the nation, with state funds at 15%, self-insurers at 23%, and the federal government at 6% [12]. The trend in the share of benefits paid by state funds has decreased in recent years, down from 20% in 2004.

Nevertheless, the state funds have created significant competition in the workers compensation insurance business in the states where they operate. State funds have a significant market share in virtually every state where they are located. In 2013, state fund market share (as measured by benefits paid) in competitive state ranged from 7% in Pennsylvania to 59% in Idaho [12].

Proponents of state funds argue that because the state funds are specialists in workers compensation they can be expected to offer more intensive levels of rehabilitation and
other services than some private insurers whose workers compensation plan is only one of several types of coverage offered. However, there are private insurers who also specialize in providing only workers compensation coverage and may offer the same level of service and expertise as the state funds.

State funds are, by law, designed to be self-supporting from their premium and investment revenue. Overhead expense ratios of both exclusive and competitive funds may be lower than expense factors for private carriers in part because of absence of some administrative costs such as agency commissions and other marketing costs. As nonprofit departments of the state, or as independent nonprofit companies, they are able to return dividends or safety refunds to their policyholders, just as some private insurers do. This further reduces the overall cost of workers compensation insurance both for the state fund as well as the private insurer that offers these types of programs [2] [3]. While lower administrative costs for state funds may reduce the cost of providing workers compensation coverage, the fact that more states have not created state funds, and some state funds have been privatized recently, suggests that private insurers are also able to provide this coverage in an efficient manner.

The evidence suggests that both state funds and private insurers are able to provide workers compensation coverage in an efficient manner.

D) Interaction of Workers Compensation Insurance with Medicare

**Background**

In 1965, Congress created the Medicare program to provide health insurance for elderly Americans. The authors of the law creating Medicare recognized that it might overlap with other private or government insurance programs—especially workers compensation insurance.

For example, a 67-year-old worker might be injured in a job accident. That worker would be entitled to have his or her medical costs reimbursed by his or her employer’s workers compensation insurer. However, that worker, being more than 65 years of age, might also be eligible for Medicare. To save Medicare costs, Congress therefore stipulated that workers compensation insurance would be primary in such a case. Medicare would be secondary and would begin to pay only if and when workers compensation benefits were exhausted.

In 1980, Congress passed the Medicare Secondary Payer Act, which stipulated that Medicare was also secondary to liability insurance. For example, if an elderly American were injured by another driver in an auto accident, the responsible driver’s insurance would be primary and Medicare secondary.

The 1980 act also introduced the notion of a “conditional payment”. In many cases persons begin incurring medical costs before eligibility to collect insurance has been
determined. In such cases Medicare will make “conditional payments” to medical providers, subject to later reimbursement by an insurer subsequently determined to be primary.

In some cases workers compensation claims are closed via a settlement which provides compensation to the injured worker for anticipated future medical payments. These payments can also overlap with Medicare. For example, a 63-year-old worker may be injured on the job. That worker is not eligible for Medicare. However, the worker’s claim may be closed with a settlement that allows for medical treatment anticipated to last five years. By the end of that time the worker will be Medicare-eligible.

Federal regulators therefore introduced (1989) the Medicare Set-Aside Allocation (MSA), in which all parties to a settlement would agree to “set aside” a portion of the workers' compensation or liability settlement to be used to pay for future medical costs related to the workers' compensation or liability injury. The MSA funds are primary over Medicare and are limited to services that are related to the injury that would be covered by Medicare after the injured party becomes Medicare eligible.

Despite these laws and regulations, the status of Medicare as secondary insurer remained mostly notional through the Twentieth Century. Medicare administrators simply did not know when Medicare eligible (or soon to be eligible) parties were collecting workers compensation or liability payments. In the absence of aggressive collection, parties had little incentive to agree to MSA’s.

**Medicare Set-Aside Allocations since 2001**

This became increasingly untenable as Medicare costs rose due to medical cost inflation and longer life expectancy. In 2001 the Center for Medicare and Medicaid Services (CMS), which administers Medicare, established its first guidelines for the review and approval of MSA’s. The implied threat was that, where MSA’s were not submitted, or not approved, Medicare would refuse payment for future care, and be more aggressive in seeking reimbursement for past conditional payments.

Since 2001, the submission and approval process for MSAs has changed several times. The changes have generally been in the direction of making MSA approval more difficult. A new sub-industry of MSA consultants has emerged to assist Third Party Administrators and insurers to evaluate settlements for MSA requirements and gain the approval of CMS.

As of 2012, CMS will review all workers compensation MSA’s where:

- The claimant is either a Medicare beneficiary and the settlement is greater than $25,000 or
- The claimant is expected to be Medicare eligible within 30 months of the settlement and the settlement or expected future medical costs and lost wages of the injury exceeds $250,000.
The CMS thresholds do not create a safe-harbor, so even smaller medical settlements should consider Medicare’s interests.

In 2016, the CMS announced that it will also begin reviewing liability and no-fault insurance MSA’s.

After an MSA is approved, the injured worker must comply with reporting requirements and use the MSA appropriately. Claimants must agree to pay their workers compensation-related medical bills, using an interest-bearing account, and to complete reporting of their payments before Medicare will make any payments for claim-related conditions.

CMS can reject or revise MSA proposals, increasing the estimated lifetime medical need, to assure that Medicare rarely becomes liable for claim-related expenses throughout the claimant’s life. Two specific issues – pharmacy costs and life expectancy – are often cited as areas of concern. With Medicare Part D, pharmacy costs were added to Medicare. In 2009, CMS issued pharmacy guidelines for MSAs, which essentially priced drugs at the retail cost level without regard to negotiated price arrangements that the insurer may have. However, many drugs commonly used for pain management are not included in Medicare Part D.

Due to industry concerns [13], in May 2010 Medicare issued clarifying language that drugs which were not included in Medicare Part D did not need to be considered in a MSA. This reduced the prescription costs in MSAs and was hailed as a significant victory in the insurance industry.

Another issue which can raise the costs of a MSA is use of a “rated age” or impaired life expectancy versus the claimant’s actual age. If a rated age is used, that means the injured person's life expectancy is less than normal which allows the settlement amount to be less than would be needed for an individual with a normal life expectancy. If CMS protocols for rated ages are not followed, CMS will recalculate the MSA using the claimant’s actual age rather than the impaired life expectancy. Due to the nuances of CMS approval, many insurers use specialists to review their MSA proposals prior to submission to CMS and to shepherd the claim through the process. Use of specialists increases the administrative costs of settling such claims.

New Reporting Requirements since 2007

On December 29, 2007, President George W. Bush signed the “Medicare, Medicaid and SCHIP Extension Act of 2007” (MMSEA). This law sought to address the problem of CMS being unaware of primary payer responsibilities, whether or not a claim involved an MSA. The law requires claim payers, known as Responsible Reporting Entities (RREs), to report claim data to the CMS. Specifically, Section 111 of the act requires the providers of liability insurance (including self-insurers), no fault insurance and workers’ compensation insurance (hereinafter “insurers”) to determine the Medicare-enrollment
status of all claimants and report certain information about those claims to the Secretary of Health and Human Services, through the CMS.

The implementation of the reporting requirement was delayed, as regulations and technology issues were ironed out, but reporting became mandatory on January 1, 2011 for insurers with workers’ compensation claims. Reporting of liability claims was phased in (with the largest claims first) beginning on January 1, 2012.

CMS uses the Section 111 data to assist Medicare in coordinating benefits and in uncovering potentially reimbursable claims. There are substantial penalties for non-compliance with the required reporting of claims - $1,000 per day per beneficiary for each day the insurer is out of compliance. This penalty is in addition to a “Double Damages Plus Interest” penalty that defendants (as primary payers) can be fined if Medicare’s right to reimbursement is ignored in any settlement. This rule applies to settlements on or after October 1, 2010.

**Property/Casualty Actuarial Implications of the Recent Changes**

From 2008 through 2010 there may have been an increase in claim closings, lump-sum payments or settlement in advance of the Section 111 reporting deadline. Some RREs may have taken the opportunity to decrease the volume of relatively minor claims that would otherwise need to have the Medicare eligibility status of the claimant determined and reports made to CMS. For actuaries reviewing both insurers’ and self-insurers’ loss data, such claim activity can distort both paid and reported losses.

Slowdowns in claim settlement rates are sometimes attributed by Workers Compensation claims professionals to the CMS changes in procedures and increased emphasis on MSAs. CMS approval of MSAs generally takes 60 to 90 days, which can contribute to a slowdown in settlements. It is possible that some portion of increasing WC medical trends is due to MSAs. In the past, claim settlements may not have specifically identified medical vs. indemnity components and the settlement costs may have been entirely attributed to indemnity. With MSAs, a clear portion of the settlement is identified as medical cost, and the CMS procedures may also have increased the average size of the settlements due to future medical considerations. However, to date there are no publicly available studies to quantify the impact on overall costs or severity trends.

In addition, for some entities, a significant risk factor could be that some injured workers currently receiving Medicare payments should be classified as workers compensation claims. The Section 111 reporting could uncover Medicare payments that should shift to workers compensation claims, causing actuarial estimates to increase as CMS files liens to recover payments. Over the last three years before claim reporting was required, the number of recovery demands from CMS increased significantly to 74,000 in 2010 from 43,000 in 2007 [14]. The number may continue increasing after 2011, or it may spike and then settle down as CMS catches up. Note that recovery can affect claims that were open in prior years, even if they are closed now.
Successful recoveries naturally increase claim severity to an insurer. The General Accounting Office (GAO) estimates total saving due to Medicare claim denials and recovery of payments of $737 million in 2008, rising to $861 million in 2011. These are costs that are borne by insurers instead of Medicare. Furthermore the GAO notes that “(A)n accurate estimate of savings could take years to determine because of the time lag between initial notification of Medicare Secondary Payer situations and recovery, the fact that not all situations result in recoveries, and the fact that mandatory reporting is still being phased in.” [15]

In 2012, new legislation affecting the interaction of Medicare and private property-casualty insurance was passed. A key provision of the Strengthening Medicare and Repaying Taxpayers Act, or SMART Act, was the implementation of a 3-year statute of limitations on Medicare conditional payment recovery. This provision became effective on July 10, 2013 and provides that an action by the federal government for recovery must be filed no later than 3 years after the date of the receipt of notice of a settlement, judgment, award, or other payment.

While the statute does not define how notice of the settlement, judgment, award or other payment is to be made to Medicare, the provision was put in place with the understanding that notice would be through Section 111 Mandatory Insurer Reporting. It is unclear then whether other types of “non-Section 111 Mandatory insurer Reporting” to Medicare will trigger the limitations period, or whether the statute of limitations will be effective in curtailing increased workers compensation claims should Medicare not cover certain claims.

**Changes in the Future?**

Section 111 reporting is in its infancy. It is uncertain how CMS will use the huge volume of data that it is collecting, whether this will lead to a significant further increase in set-asides or recovery demands, and whether the statute of limitations will temper claim volume. It may take years for changes to be fully apparent, especially for liability lines for which mandatory reporting didn’t begin until 2012 and will be phased in.
Notes:

Reinsurance contracts held: an example of proportionate reinsurance coverage

IFRS 17 Insurance Contracts
Introduction

This example illustrates the requirements in IFRS 17 *Insurance Contracts*:

a) applied to a group of underlying insurance contracts; and

b) applied to a group of reinsurance contracts held that provides proportionate coverage for that group of underlying insurance contracts

This example demonstrates that:

- the measurement of a group of reinsurance contracts held is consistent with the measurement of any underlying insurance contracts
- the timing of cash flows do not directly affect the recognition of reinsurance income or expenses
Further information
Paragraphs 60-70 of IFRS 17 Insurance Contracts
Paragraphs BC296-BC315 of the Basis for Conclusions on IFRS 17 Insurance Contracts
Webcast Reinsurance contracts held available at: go.ifrs.org/IFRS-17-implementation
Assumptions

- IFRS 17 general model (not PAA)
- Risk adjustment for non-financial risk is nil
- Discount rate 0%
- Services are provided by the insurer evenly over the contract term for each contract
- All events occur as expected at initial recognition

Further information
The objective of this example is to demonstrate the mechanics of the IFRS 17 requirements for reinsurance contracts held. For simplicity, a number of assumptions have been made. This example is not intended to reflect a real fact pattern.
Group of underlying insurance contracts
**Further information**

1 Contract A is issued on 1 January in year 1
2 Contract B is issued on 30 June in year 1
3 Contract C is issued on 31 December in year 1
4 Initial recognition of the group of insurance contracts: 1 January in year 1 is the beginning of the coverage period of the group of insurance contracts (paragraph 25(a) of IFRS 17). The coverage period for the group of insurance contracts is from 1 January in year 1 to 30 December in year 2. For simplicity, in this example the coverage period is referred as 2 years.
Further information
All events occur as expected at initial recognition.
1 Premiums of 300 are expected on day 1 for each of the 3 underlying insurance contracts.
2 Claims of 600 are expected for the group of insurance contracts. Claims are incurred equally by each of
the 3 underlying insurance contracts. For each underlying insurance contract, claims occur evenly over
the 1 year contract term as services are provided and are paid immediately after incurred. The claims
cash flows at each reporting date can be analysed as:
• Year 1 30 June – Contract A 100
• Year 1 31 December – Contract A 100 + Contract B 100
• Year 2 30 June – Contract B 100 + Contract C 100
• Year 2 31 December – Contract C 100
Further information

1 At 1 January in year 1 the group is recognised and consists of the cash flows for Contract A only.
   - FCF: premiums of 300 for Contract A are received on 1 January. The fulfilment cash flows at this date reflect expected claims of 200.
   - CSM: the CSM of 100 at initial recognition is the amount that results in no income or expenses arising from the initial recognition of the fulfilment cash flows of 200 and the premiums received on that date of 300.

2 At 30 June in year 1 the cash flows for Contract B are added to the group.
   - FCF: premiums of 300 for Contract B are received on 30 June. The fulfilment cash flows reflect expected claims of 300 (opening balance of 200 plus 200 expected claims for Contract B minus 100 claims paid in the period).
   - CSM: the balance of the CSM is 150 (opening balance of 100 plus 100 for Contract B minus 50 recognised as revenue in the period (see profit or loss slide 9)).

3 At 31 December in year 1 the cash flows for Contract C are added to the group.
   - FCF: premiums of 300 for Contract C are received on 31 December. The fulfilment cash flows reflect expected claims of 300 (opening balance of 300 plus 200 expected claims for Contract C minus 200 claims paid in the period).
   - CSM: the balance of the CSM is 150 (opening balance of 150 plus 100 for Contract C minus 100 recognised as revenue in the period).

4 At 30 June in year 2 no new cash flows are added to the group.
   - FCF: the fulfilment cash flows reflect expected claims of 100 (opening balance of 300 minus 200 claims paid in the period).
   - CSM: the balance of the CSM is 50 (opening balance of 150 minus 100 recognised as revenue in the period).

5 At 31 December in year 2 the group is derecognised.
   - FCF: the fulfilment cash flows reflect expected claims of 0 (opening balance of 100 minus 100 claims paid in the period).
   - CSM: the balance of the CSM is 0 (opening balance of 50 minus 50 recognised as revenue in the period).

**Further information**

\(^1\) In this example, for each underlying insurance contract, claims are incurred evenly over the 1 year contract term as services are provided and are paid immediately when incurred. All events occur as expected. See cash flows slide 7.

\(^2\) At 30 June in year 1, the CSM before recognising any amount in profit or loss is 200. The CSM recognised for the period of six months ending 30 June in year 1 is 50. 50 reflects the amount allocated to coverage provided in the period (contract 1 was in force for six months) while the remaining 150 reflects coverage expected to be provided in the future (contract 1 is expected to be in-force for six months and contract 2 expected to be in force for a year). The CSM recognised in the remaining periods is determined in the same way.
Reinsurance contract held: timing of cash flows match timing of cash flows for the underlying insurance contracts
The reinsurance contract held is recognised on 1 January in year 1. In this example the reinsurance contract held, as a single contract, is identified as a group of insurance contracts. In this example, the group is referred to as the reinsurance contract held.

Initial recognition of reinsurance contract held: 1 January in year 1 is the beginning of the coverage period for the reinsurance contract held and is also the initial recognition of the first underlying insurance contract added to the group (paragraph 62(a) of IFRS 17). The coverage period for the reinsurance contract held is equal to the coverage period for the group of underlying insurance contracts, from 1 January in year 1 to 30 December in year 2. For simplicity, in this example the coverage period is referred as 2 years.
Further information

1 Premiums expected to be paid to the reinsurer are equal to the premiums received from the policyholder on the underlying insurance contracts. Premiums are expected to be paid to the reinsurer on the same day that premiums are received from the policyholder.

2 Claims expected to be received from the reinsurer are equal to the claims expected to be paid to the policyholder on the underlying insurance contracts. Claims are expected to be received from the reinsurer on the same day that claims are paid to the policyholder.

See slide 7 for the cash flows arising from the group of underlying insurance contracts.
## Further information

1. The fulfilment cash flows of the reinsurance contract held reflect all future cash flows expected to arise within the boundary of the reinsurance contract held. In this example, those cash flows relate to all underlying insurance contracts expected to be covered by the reinsurance contract including underlying insurance contracts that have not been issued yet.

2. The CSM for the reinsurance contract held represents the net cost of purchasing reinsurance.

3. At 1 January in year 1 the reinsurance contract held is recognised.
   - FCF: the fulfilment cash flows are 0 (opening balance of 0 plus 900 expected premiums minus 600 expected claims minus 300 premiums paid relating to Contract A).
   - CSM: the CSM of 300 at initial recognition is the amount that results in no income or expenses arising from the initial recognition of the fulfilment cash flows of 0 and the premiums paid on that date of 300.

4. At 30 June in year 1:
   - FCF: the fulfilment cash flows are 200 (opening balance of 0 minus 100 claims received plus 300 premiums paid relating to Contract B).
   - CSM: the balance of the CSM is 250 (opening balance of 300 minus 50 recognised as reinsurance contract expenses in the period (see profit or loss slide 14)).

5. At 31 December in year 1:
   - FCF: the fulfilment cash flows are 300 (opening balance of 200 minus 200 claims received plus 300 premiums paid relating to Contract C).
   - CSM: the balance of the CSM is 150 (opening balance of 250 minus 100 recognised as reinsurance contract expenses in the period).

6. At 30 June in year 2:
   - FCF: the fulfilment cash flows are 100 (opening balance of 300 minus 200 claims received)
   - CSM: the balance of the CSM is 50 (opening balance of 150 minus 100 recognised as reinsurance contract expenses in the period).

7. At 31 December in year 2 the reinsurance contract held is derecognised.
   - FCF: the fulfilment cash flows are 0 (opening balance of 100 minus 100 claims received).
   - CSM: the balance of the CSM is 0 (opening balance of 50 minus 50 recognised as reinsurance contract expenses in the period).
Further information

1 The breakdown of the reinsurance premiums amount is given in the slide to explain the results in this example. Applying IFRS 17, revenue does not arise from reinsurance contracts held. Accordingly, the requirements for revenue, including the related disclosures, do not apply.

2 In this example, claims received from the reinsurer are equal to the claims paid to the policyholder on the underlying insurance contracts. Claims are received from the reinsurer on the same day that those claims are paid to the policyholder. All events occur as expected. See expected cash flows - slide 12.

3 To determine the amount of the contractual service margin to be recognised in profit or loss in the period for the reinsurance contract held, in this example, the insurer considers the relevant facts and circumstances related to the underlying insurance contracts and determines that the amount and timing of services received under the reinsurance contract held are consistent to the amount and timing of services provided under the underlying insurance contracts (see slide 9).
Further information

FCF: in this example, the cash flows for the reinsurance contract held are equal to the cash flows for the group of underlying insurance contracts and they occur at the exact same time.

CSM: in this example, the insurer provides service equally over the contract term for each underlying insurance contract. In this example, the insurer determines that the amount and timing of services received under the reinsurance contract held are equal to the amount and timing of services provided under the underlying insurance contracts.

As a result of the above, the balance of the reinsurance contract asset is equal to the balance of the insurance contract liability.
Further information

This is a simplified example of 100% proportionate reinsurance coverage. In this example, the services provided by the insurer under the underlying insurance contracts in each period are consistent with the services received from the reinsurer under the reinsurance contract held in each period. Also, the consideration to which the insurer expects to be entitled in exchange for the services provided under the underlying insurance contracts is equal to the consideration the insurer expects to pay to the reinsurer in exchange for the services received under the reinsurance contract held.

As a result, there is a nil impact on the statement of profit or loss.
Reinsurance contract held: cash flows are settled net at the end of the coverage period
### Cash flows

Same fact pattern, expect that all reinsurance contract cash flows are settled net at the end of the coverage period

<td>Claims</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td><strong>Net cash outflow</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Further information**

A net amount of 300 is expected to be paid to the reinsurer at the end of the coverage period (900 premiums minus 600 claims).
Further information

1 The fulfilment cash flows at each reporting date is 300 until the end of the coverage period. This reflects that the insurer expects to make one payment of 300 to the reinsurer at the end of the coverage period.

2 The contractual service margin is measured and recognised in the same way as in the previous example (see slides 13–14) because the services provided under the reinsurance contract held are the same. The only difference in this example is the timing of the cash flows.

3 In this example, the balance is a reinsurance contract liability because the expected future cash flows are a net outflow.
Further information
The statement of profit or loss in this example is the same as the statement of profit or loss in the previous example (see slides 13–14) because the services provided under the reinsurance contract held are the same. The only difference in this example is the timing of the cash flows. The timing of cash flows may impact insurance finance income or expenses however, for simplicity in this example, the discount rate is 0%.

<tr>
<td>Net reinsurance contract expenses</td>
<td>(50)</td>
<td>(100)</td>
<td>(100)</td>
<td>(50)</td>
</tr>
</tbody>
</table>
Further information

FCF: in this example, the cash flows for the reinsurance contract held are equal to the cash flows for the group of underlying insurance contracts, however the cash flows occur at different times.

CSM: as with the previous example, the insurer provides service equally over the contract term for each underlying insurance contract. Also in this example, the insurer determines that the amount and timing of services received under the reinsurance contract held are equal to the amount and timing of services provided under the underlying insurance contracts.

As a result of the above, the balance of the reinsurance contract liability is not equal to the balance of the insurance contract liability. This reflects the fact that, at each reporting period, the expected future cash flows under the reinsurance contract held are different to the expected future cash flows under the group of underlying insurance contracts.

**Further information**

See slide 16.
In practice

- In practice it is likely that there will be differences between the cash flows arising from:
  
  a) the rights and obligations of the underlying insurance contracts; and
  b) the rights and obligations of the reinsurance contract held.

- These differences may exist, for example, because:
  
  a) the timing of cash flows can vary, which can also impact insurance finance income or expenses; or
  b) the reinsurer prices the reinsurance contract differently to the pricing of the underlying contracts.

Comment on our work
- go.ifrs.org/comment
1. Introduction

Professionalism for the actuarial profession means:
- the application of specialist actuarial knowledge and expertise;
- the demonstration of ethical behaviour, especially in doing actuarial work; and
- the actuary’s accountability to a professional actuarial association or similar professional oversight organisation on the basis of a code of conduct.

The distinguishing feature of a profession that sets it apart from a trade, a craft, a guild or a syndicate is the overriding interest of the individual professional in the public well-being.¹

This definition of professionalism is derived from the following high-level principles of professionalism, which are discussed in detail in this report:

A. Knowledge and expertise  
B. Values and behaviour  
C. Professional accountability

These principles are discussed below.

2. Principle A: Knowledge and Expertise

“An actuary shall perform professional services only if competent and appropriately experienced to do so”².

This principle of Knowledge and Expertise is supported by the following elements:
- Specialist knowledge  
- Professional communication  
- Required education  
- Continuing professional development

2.1. Specialist knowledge

The existence of a distinct actuarial profession globally is a result of actuaries’ specialist knowledge and expertise.

An actuary’s clients may include governments, community organizations, funds, industries, businesses and individuals.

² Source: IAA Internal Regulations 2.2.2 (a) (iv)
Actuaries are equipped to help their clients make informed choices and develop efficient solutions to safeguard their future in an ever-changing world.

Actuaries provide realistic, innovative and numerate solutions to complex financial and other measurable problems, sometimes over long time horizons and for uncertain events, using a control process to monitor and refine solutions over time.

Actuaries are experts in modelling complex future events, often developing models from first principles, and are experts in understanding and analysing data. Uses of models include sensitivity analysis and scenario testing in order to communicate the model dynamics and the implications of the model results.

Actuaries apply this skill set within a professional environment which ensures, through adherence to the principles of professionalism, the delivery of competent work, professional ethics, life-long learning and professional standards and discipline. This allows actuaries to make an important contribution to public debate in matters affecting the interests of the public.

2.2. Professional communication

Effective and appropriate communication is an essential part of all actuarial work. Communication needs to be clear and appropriate to the circumstances and the intended audience, and to satisfy whatever applicable standards of practice exist and apply to the individual actuary’s situation. Appropriate communication includes the ability of the actuary to:

- Document the work done.
- Communicate the basis and the outcome of the work to other actuaries.
- Communicate with others who contribute to the work with courtesy and respect.
- Communicate the assumptions, outcome and implications of actuarial work to the actuary’s superior or client.
- Prepare material for presentation.

Actuarial work requires an awareness of the business context to both determine the correct response and effectively communicate results. An actuary therefore needs to ensure that the advice given is communicated effectively, so as to avoid misunderstanding by clients who may not have relevant skills or knowledge.

One of the most important factors in developing and improving communication skills is education. Options that an FMA may consider for furthering communication skills of their member actuaries include offering professionalism courses and continuing professional development focusing specifically on communication skills.

2.3. Required education

Actuaries have a large and specialist skill set, breadth of knowledge, and training.

The IAA, in its Internal Regulations for membership requirements for Full Member Associations (FMA), sets out criteria that include an education syllabus, code of professional conduct, formal discipline process and governing documents of the FMA.

2.4. Continuing Professional Development

Actuaries need to maintain their knowledge, expertise and skills. Actuaries can work in a variety of areas and need to be competent in their chosen area(s) before providing advice. Over time there could also be changes in techniques, regulations, professional standards and codes of professional conduct with which actuaries need to keep up to date.
Continuing Professional Development (CPD) could include analysis of case studies, general topics on ethics and analysis of current problems, so as to enhance the actuary’s understanding of current technical and professional issues.

Lessons can also be learned from the interaction with other professions, knowing their codes of conduct, exchanging points of view, as well as having joint sessions analysing current business or society issues. This issue is important because the professional actuary will often operate in multi-disciplinary teams.

FMA’s are encouraged to adopt a CPD strategy. CPD may be supported by a compliance program administered by the actuary’s membership association.

3. Principle B: Values and Behaviour

“An actuary shall perform professional services with integrity, skill and care. An actuary shall act in a manner that fulfils the profession’s responsibility to the public. An actuary shall act in a manner that upholds the reputation of the actuarial profession.”

This principle of Values and Behaviour is supported by the following elements:

- Ethical behaviour
- Integrity
- Independent advice
- Trust and reputation
- Responsibility to the public

3.1. Ethical behaviour

Full Members of the IAA must have a code of professional conduct consistent with the principles in the Internal Regulations. The definition of professionalism should explicitly incorporate a reference to ethical behaviour.

For example “A member shall act honestly, with integrity and competence, and in a manner to fulfil the profession’s responsibility to the public and to uphold the reputation of the actuarial profession.”

Differences of views among FMA’s on what constitutes ethical behavior can be accommodated. For example, in some areas individuals are encouraged to expose improper activity (“whistle-blowing”), while in other areas issues are resolved by indirect means.

3.2. Integrity

The foundation of good behaviour is integrity. Consequently, the list of IAA requirements in regulation 2.2.2 (a)(i) begins:

An actuary shall perform professional services with integrity, skill and care

Many associations give prominence to integrity in their codes of conduct.

Other professions also describe integrity as the cornerstone of professional ethical behaviour. The IAA Professionalism Committee supports these views.

---

3 Source: IAA Guidelines on Continuing Professional Development (CPD), esp. chapter 2.3
4 Source: IAA Internal Regulations 2.2.2 (a)(i) and (ii)
5 This definition is used by the Canadian Institute of Actuaries. Definitions of other associations can be referenced on the IAA Professionalism Committee Resources page. See Professionalism Committee Resources.
3.3. Independent advice

An important aspect of professionalism and ethical behaviour is the ability of the actuary, whether employed or not, to express an independent opinion or provide unbiased independent advice, where the circumstances require this. The former Groupe Consultatif, now Actuarial Association of Europe (AAE), produced a discussion paper in 2010 on the topic of operational independence in the context of the actuarial function under Solvency II. This made a number of important points about independence—here understood as freedom from undue influence:

“… independence ... might be described as the ability to analyse and to make relevant decisions ... without being unduly or inappropriately controlled, constrained or influenced by the management or Board (or Boards) of the company or by any other function.

... independence is compromised if there is any form of pressure on the persons carrying out the actuarial function to make a particular decision on the data, methods, assumptions or results of their work.

... independence ... involves the exercise of professional judgment, based on education, experience and ethical standards, and the ability to analyse all relevant aspects of the situation in an impartial way to come to an independent conclusion.

... independence is also enhanced through transparency and disclosure of summarised data and results, including reporting on the methodologies adopted, the assumptions used and the thought processes by which they were arrived at.

... independence involves the person in question taking personal responsibility and should be demonstrated by personally signing a report which certifies what has been done.

Impartiality and independence are enhanced by a requirement to adhere to professional standards, including ethical and governance standards. Typically ethical standards might include specific requirements to:

- Ensure competence in relation to the task in question;
- Perform the function with integrity skill and care; and

Carry out the role with impartiality.”

3.4. Trust and reputation

The Codes of Conduct which underpin the professionalism of member associations are primarily designed to create and maintain trust in the work of actuaries among the users of actuarial advice. Trust and reputation are qualities that take many years to build up but can be destroyed very quickly, even by the actions of a single individual.

To this end, many Codes require the actuary not to do anything that might harm the reputation of the actuarial profession or his or her association. Some Codes also encourage the actuary to strive to enhance the profession’s reputation at all times. Such Code provisions create individual responsibility to the profession to which an actuary belongs.

3.5. Responsibility to the public

The essential element that sets a profession apart from a trade, craft or guild is the overriding interest of the professional in protection of the public from unsound practices, whether or not that comes into conflict with the immediate objective of earning his or her living. Professionals owe their status and recognition in society to the trust that the public places in them.

Individual actuaries fulfill their responsibility to the public and to the profession by upholding the values and standards of the profession, fulfilling statutory roles, avoiding conduct which

---

6 Source: “Independence – A Discussion Paper”, see Professionalism Committee Resources - Principles of Professionalism
could bring the profession into disrepute and supporting the professional organization that provides public interface with the profession in the actuary’s jurisdiction. The IAA membership Regulations require provisions in members’ Code of Conduct to be consistent with the principle that  

"An actuary shall act in a manner that fulfils the profession’s responsibility to the public".

They also state that "The Full Member [Association] may provide more specific guidance if it wishes to do so (for example, it may indicate that an actuary could consider advising a client or employer where a proposed course of action would, in the opinion of the actuary, be contrary to the public interest".  

Provided an actuary meets the requirements of law as well as his or her actuarial association’s code of professional conduct and applicable professional standards, then the actuary will be considered to have met his or her responsibility to the profession and to public.

### 4. Principle C: Professional Accountability

Actuaries have professional responsibility to clients and/or employers, the public and to their Full Member Association. In particular,  

"An actuary is responsible for ensuring that the actuary’s work conforms to applicable practice standards in the actuary’s area of work. An actuary must take into account relevant mandatory practice-related guidance issued or endorsed by the actuary’s association, and may take into account any non-mandatory practice-related information that is so issued or endorsed."  

The Full Member Association holds the individual actuary accountable in so far as the actuary is subject to the FMA's disciplinary process.

This principle of Professional Accountability is supported by the following elements:

- Entry and qualification standards
- Code of Conduct / Standards of practice
- Disciplinary process

#### 4.1. Entry and qualification standards

Each Full Member Association has its own requirements to admit members and to determine who among them is qualified to do what kind of actuarial work. The detailed requirements vary from country to country. The IAA Education Syllabus as well as the IAA Education Guidelines provide additional background as stipulated in the IAA Internal Regulation 2.2.2 (d).

The admission of members to an FMA will in all cases be under the control and authority of the FMA, based on the FMA’s requirements. This may include passing exams established by the FMA, as well as being subject to professional requirements established by the FMA or another regulatory body. Some FMAs will also require completion of work-based skills. The FMA’s applicable code of professional conduct must be made available to the actuaries who are members of the FMA.

Note that the IAA Education Guidelines do not prescribe either the education process or the assessment methods.

Also note paragraph 2.4 on Continuing Professional Development.

---

7 Source: IAA Internal Regulations, 2.2.2 (a) (i) and (ii)  
8 Source: IAA Internal Regulations, 2.2.2 (a) (i)  
9 Source: IAA Internal Regulations, 2.2.2 (a) (v)  
10 Source: IAA Internal Regulations, 2.2.2 (a)
4.2. Code of Conduct / Standards of practice

Professional organizations must have adopted rules that govern the conduct of their members as they undertake the specialized work for which they have been, and continue to be, trained.\(^{11}\) To this end, the IAA requires its Full Member Associations’ Codes of Conduct to be consistent with, the professional principles as set out in IAA Internal Regulation 2.2.2 (a). These principles cover:

i. integrity

ii. public interest

iii. confidentiality

iv. qualification and competence

v. conformity with professional standards

vi. taking responsibility

vii. disclosure

viii. conflict of interest

ix. consultation with previous actuary

x. disclosure of related remuneration

xi. subjection to disciplinary procedures.

IAA member associations may incorporate additional requirements in their codes of conduct as long as these do not lower any of the obligations enumerated in Section 2.2.2(a) of the Internal Regulations.

All members of the actuarial association are required to adhere to their Code of Conduct and failure to do so must be considered a matter for disciplinary consideration. To aid members in their adherence to the Code of Conduct, it must be made readily available to all members of the association and members are to be encouraged to review it from time to time.\(^ {12}\)

The Code of Conduct will also require members to comply with the applicable practice standards. The actuary must take into account relevant mandatory practice-related guidance issued or endorsed by the actuary’s association, and may take into account any non-mandatory practice-related information that is so issued or endorsed.\(^ {13}\)

4.3. Disciplinary process

To ensure FMAs are serious about their Code of Conduct and members’ adherence, FMA must have a formal process of professional discipline for transgressions of the Code. The discipline process must be applied, and be seen to be applied, equitably.\(^ {14}\)

The IAA has adopted a short list of criteria to which the discipline processes of Full Member Associations must conform, as specified in IAA Internal Regulation 2.2.2 (b). These are:

"The Full Member must have a formal discipline process in place, including the following:

i. There is a complaint process accessible to anyone affected by an actuary’s work and the actuary’s professional peers.

ii. There is due process of defense available to the actuary complained against, and the actuary’s rights are fully respected.

iii. There is an objective formal appeal process independent of the body that has ruled at the

\(^ {14}\) Source: IAA Internal Regulation 2.2.2 (b)
iv. There are available sanctions appropriate to the seriousness of the violations committed, including termination of membership in the association.

v. The process shall enable the association to give appropriate notice and information to the public of the results of the complaint process where any penalty is imposed, including providing information to other actuarial associations. Any notice to the public shall be consistent with the discipline process.”

5. Adoption

This document is the result of a formal review of the “Principles of Professionalism” by the Professionalism Committee of the IAA.15 The original version was formally adopted by Council on 23 January 2012, after consultation with the IAA’s FMAs.

The document has been approved by the IAA Executive Committee on 2 August 2017 and ratified by IAA Council on 7 October 2017 as non-binding guidance to aid member associations in their development and maintenance of Professionalism standards.

15 Following the “IAA Framework for the production of Professionalism Guidelines”
PG2 - Principles in relation to the Governance of International Actuarial Work

This paper has been prepared by the IAA Professionalism Committee for information to assist Member Associations in this increasingly important area. It is not a model standard, nor is any change to associations’ codes of conduct expected at the time of writing. This paper may also be of interest to individual actuaries undertaking International Actuarial Work.

1. **Definition of “International Actuarial Work”**

1.1 International Actuarial Work is defined as work that is under the jurisdiction or regulation of one country, but is carried out by an actuary whose principal jurisdiction of practice or the jurisdiction of their professional membership is in a different country.

1.2 The “governance” of International Actuarial Work refers to the regulation and supervision of the actuary’s conduct and work by member associations of the International Actuarial Association (IAA).

1.3 International Actuarial Work is broadly therefore actuarial work in relation to which the law/standards/regulatory frameworks of more than one country are relevant and material. More specifically, it is taken to include ‘actuarial work’\(^1\) in relation to which the legal/regulatory requirements of more than one legal jurisdiction or IAA member association\(^2\) are relevant and material.

1.4 The following are a set of principles that might be applied by IAA member associations, with a view to avoiding or addressing the potential for inconsistency, duplication or gaps in relation to the governance of International Actuarial Work.

2. **Proposed Principles**

2.1 **Qualification, Codes and Standards**

2.1.1 Adherence to Codes of Conduct helps to ensure that actuaries are competent to undertake work for which they are responsible, and have an appropriate understanding of relevant legal and regulatory requirements applicable to them and to that work.

---

\(^1\) ‘Actuarial work’ is assumed in this context to be defined broadly, to include any work done by members of IAA associations in their capacity as actuaries, including work done for the purposes of providing ‘Actuarial Services’, as defined in ISAP 1.

\(^2\) It is recognized that the regulatory jurisdiction of IAA member associations will usually arise from membership, and may not necessarily or primarily depend upon geographic/territorial considerations. Equally, it is recognized that in certain geographic territories there may be more than one IAA body which has jurisdiction. It is envisaged that the principles set out in this paper might, according to the circumstances, also be relevant in that context i.e. where there is more than one relevant legal or regulatory framework operating within a single geographic area or territory.
2.1.2 Except to the extent that they are inconsistent with relevant mandatory legal or regulatory requirements, actuaries therefore apply the code and standards and satisfy the educational and qualification standards\(^3\) and requirements, where applicable, of each of the full IAA member bodies of which they are a member. Where appropriate, actuaries also follow any applicable local qualification standards and standards of practice.

2.1.3 Where there is material inconsistency between the codes, qualification standards and/or practice standards which an actuary would otherwise be required to apply to a piece of work, or between those standards and others which are more relevant to the work in question, reasonable judgment is exercised by the actuary in determining which code, qualification standards and practice standards to apply, and the extent to which they apply, having regard to all of the relevant circumstances, including the following considerations:-

2.1.3.1 The context in which, and purpose for which, the work is being provided;
2.1.3.2 Relevant market expectations and norms in the context in question; and
2.1.3.3 The need to safeguard the interests of the client and of the public in relation to the work in question.

2.1.4 It may be appropriate for actuaries to advise and/or justify to their clients as to the code and standards that have been applied to their work.

2.1.5 Associations are encouraged to include consideration of international and cross-border practice in the development and maintenance of their code, qualification standards and (where applicable) standards of practice. Ideally this is done so as to reduce or avoid situations of direct conflict with applicable codes and standards applied to their members and the members of other IAA associations.

2.2 Continuing Professional Development (CPD)

2.2.1 Many actuarial organizations or other actuarial authorities include a requirement for continuing professional development in their requirements for membership or in their qualification standards. These requirements may range from highly prescriptive requirements with numerous rules, to general principle-based requirements.

2.2.2 In general, compliance is expected with the CPD regimes of every full IAA member association of which the actuary is a member. The actuary may also be required to fulfill an organization’s CPD requirement in order to fully meet a local qualification standard. This may create difficulties to the extent CPD undertaken to fulfill one organization’s requirement cannot be used to help fulfill another organization’s CPD requirement.

2.2.3 Associations are therefore encouraged where appropriate to recognize CPD undertaken in fulfilment of the requirements of another full IAA member association and to recognize compliance with the CPD regime of that other association as fulfilling their own requirements, including any such requirement incorporated into qualification standards. This suggestion is not meant to imply that an association should lower the level of acceptable actuarial practice.

2.2.4 Where possible and appropriate, member associations are encouraged to avoid duplicative requirements, either in relation to the undertaking of the substantive CPD itself, or in relation to the compliance burden associated with the regulation of CPD.

---

\(^3\) By ‘qualification standards’ we mean the standards or requirements, imposed by a body of appropriate authority, which actuaries are required to satisfy in order to be considered qualified to perform the work in question. These may include initial educational requirements required to obtain sufficient knowledge to practice (broadly or in a particular practice area), CPD requirements and/or experience requirements. In some jurisdictions these may include, for example, practising certificates.
2.3 Disciplinary Investigation and Enforcement

2.3.1 Actuaries are subject to the professional disciplinary jurisdiction of those IAA member association(s) of which they are a member. Each association retains its jurisdiction to deal with disciplinary matters in relation to its members.

2.3.2 Member associations are however encouraged to take appropriate steps in order to facilitate the sharing of relevant information with other IAA associations in relation to disciplinary proceedings, and to cooperate where appropriate in relation to the disciplinary investigations and/or proceedings of other member associations. Sharing of information should take into account any relevant laws, regulations and court rulings in respect of the entitlement of members and third parties (including actuarial clients) to privacy, confidentiality and/or data protection.

2.3.3 Member associations might in particular, while mindful of the overriding importance of procedural fairness, seek to coordinate their disciplinary arrangements in a number of ways:

2.3.3.1 They might put in place a formal cross-border discipline arrangement with another association or associations. This envisages in effect that one association (Association 1) assumes, in specific circumstances, some defined formal (legal) responsibility for undertaking investigations as to violation of actuarial standards in its relevant jurisdiction and/or disciplinary proceedings in relation to the members of another association (Association 2). (For example, and most obviously, where the proceedings relate to the conduct of the member of Association 2, whilst practising in the geographic jurisdiction associated with Association 1). A version of this approach is currently adopted, for example, by the North American actuarial associations.

2.3.3.2 A similar, but less formal, arrangement would not involve the conferral of actual legal jurisdiction on Association 1. Instead, Associations 1 and 2 might instead agree simply to provide mutual assistance in relation to disciplinary matters, including the sharing of relevant information, and support in the gathering of evidence for the purposes of disciplinary investigations. This would not necessarily however envisage the conferral of any formal decision-making authority on Association 1, in relation to the members of Association 2. Arrangements of this sort are known to exist between a number of associations, and might be effected for example by some form of Memorandum of Understanding.

2.3.3.3 In certain circumstances, more than one association may have jurisdiction and be required to undertake separate disciplinary proceedings. It may in these circumstances be appropriate to consider the coordination of disciplinary investigations and/or proceedings (so as to avoid unnecessary duplication from a practical perspective). It may be appropriate for one association to take the lead in relation to any substantive investigation/proceedings. This may, for example, be the most relevant association, having regard to the alleged conduct and to the related evidence in the case. Member associations are encouraged to

---

4 The Canadian Institute of Actuaries (CIA) and the U.S.-based organizations have entered into a cross-border discipline agreement that provides, in essence, that if a member of a U.S.-based organization is accused of breaching Canadian professional standards of conduct, practice, or qualification when practising in Canada, the CIA will investigate the matter and, if the CIA finds that the actuary has committed such a breach, the CIA will so notify the relevant U.S.-based organization(s). Similarly, if a question arises concerning a CIA member’s practice in the United States, the question will be investigated by the U.S.-based Actuarial Board for Counseling and Discipline, and the relevant U.S.-based organization(s) will notify the CIA of any determination of breach of U.S. professional standards of conduct, practice, or qualification.
enter into a dialogue with other relevant association(s), where applicable, at the outset of such a case, in order appropriately to co-ordinate the investigation and proceedings, having regard to all of the circumstances.

2.3.3.4 Member associations will also wish to consider what weight or recognition they can appropriately give to the disciplinary findings or determination of another association. So, for example, certain European associations are known to have in place provisions which permit a degree of weight or reliance to be placed on the formal findings of another association, thereby avoiding to some extent the need for a further potentially duplicative inquiry into the relevant factual circumstances.

2.3.3.5 A further variant would envisage arrangements by which a joint disciplinary panel or committee is convened, comprising appropriate representatives or appointees from each of the associations involved. This could enable a single hearing by a jointly recognized panel, the decision of which is formally recognized (and enforced) by each association. This model has again been adopted for certain purposes in North America and avoids the necessity for multiple hearings in relation to the same member and conduct.

2.3.4 In the longer term, there may be value in reviewing the scope for a greater level of consistency/harmonization between the specific tests/thresholds applied by associations in establishing the necessity for disciplinary action.

This paper was approved by the Professionalism Committee on 28 March 2014. It was adopted as PG2 by Council on 7 October 2017.
A Global Framework 
for Insurer Solvency Assessment

Preface

Acting in support of the International Association of Insurance Supervisors (IAIS) the Insurance Regulation Committee of the International Actuarial Association (IAA) formed the Insurer Solvency Assessment Working Party (WP) in early 2002 to prepare a report on insurer solvency assessment. This Report represents the culmination of that mandate and is meant to assist in the development of a global framework for insurer solvency assessment and the determination of insurer capital requirements. The IAA considers this Report to represent useful educational material. The Report is not intended to express a unique or absolute point of view with regard to the issues which surround the topic of insurer solvency assessment. The materials contained in the Report will need to be enhanced over time in light of new developments.

In the course of its mandate, the WP made several presentations on the work of the WP before a variety of insurance supervisory and professional actuarial meetings. The WP met with the IAIS Technical Sub-Committee on Solvency and Other Actuarial Issues, the insurance internal market directorate of the European Commission, the Conference of European Insurance Supervisors, as well as numerous professional actuarial associations. Feedback from these presentations has been both positive and constructive.

The WP wishes to extend its thanks to all those individuals and organizations who have provided commentary on this report. Of particular note are the contributions of the Casualty Actuarial Society and the Society of Actuaries who have provided assistance with the editing of this report.

The WP members also extend their sincere gratitude to those who have contributed to this report with their wisdom, insight and practical examples. In particular, we would like to recognize the work of Peter-Paul Hoogbruin, Christoph Hummel, John Manistre, Greg Martin, Ulrich Mueller, Martin Paino, Les Rehbeli, Shawn Stackhouse, Erik von Schilling and Brent Walker for their contributions to this report. The Chair expresses special thanks to Julie Silva for her special talents in assembling and formatting this extensive report and set of appendices. Finally, the WP members appreciate the support of their employers and actuarial associations throughout this project. The Working Party looks forward to wider discussion of the issues discussed in this report.

IAA Insurer Solvency Assessment Working Party

Toshihiro Kawano (Japan)       Bob Wolf (U.S.)
1. Introduction

1.1 One of the current initiatives of the International Association of Insurance Supervisors (IAIS) is to develop a global framework for insurer capital requirements. Acting in support of the IAIS, the International Actuarial Association (IAA) has formed an Insurer Solvency Assessment Working Party to prepare a paper on the structure for a risk-based solvency assessment system for insurance. The terms of reference of the Working Party (WP) are as follows:

- The WP should describe the principles and methods involved in quantifying the total funds needed to provide a chosen level of confidence to policyholders and shareholders that the insurer’s policyholder obligations will be met.
- The paper should be specific and practical enough that its recommended principles and methods could be used as a foundation for a global risk-based solvency capital system for consideration by the IAIS.
- The paper should, starting from a coherent risk framework, identify risk measures that can be explicitly or implicitly used to measure the exposure to loss from risk and also any risk dependencies. The paper should also identify measures that are not effective in this regard.
- In balancing its focus between practical versus sophisticated methodologies, the working party will place greater weight on those methodologies with the greatest likelihood of practical implementation. However, since simple methodologies that can be applied to many insurers in a territory or across territories may prove insufficiently reliable or capital efficient, the WP should consider whether risk models developed internally by insurers can provide a useful and reliable approach.

1.2 The focus of prudential regulation and supervision of financial institutions is usually defined as the protection of the rights of policyholders and depositors. Since this includes oversight of the continuing ability of insurance companies to meet their contractual and other financial obligations to their policyholders, the supervisor has a strong interest in the continuing solvency of both insurers and reinsurers under its jurisdiction. The application of this report is intended for both direct writing insurers as well as reinsurers. Throughout this report, “insurer” will be used to refer to both direct writing insurance companies as well as to reinsurers.

1.3 This report deals with methods the supervisor might use to assess the current financial position as well as to understand the possible future financial positions of insurers. Its primary focus is on capital requirements and practices that strengthen the ability of a company to successfully manage its risk in a way to lessen its need for capital.

1.4 Working within the terms of reference, this report is organized as follows:

- Section 3 – “Capital Requirements” reviews the purpose of capital and important principles for the determination of appropriate levels of risk; describes defensive tactics for solvency protection and their role in the design of a capital requirement
- Section 4 – “Framework for Solvency Assessment” provides an introduction to the WP’s suggested approach towards insurer capital requirements
- Section 5 – “Insurer Risks” describes the key insurer risks and the key considerations in measuring them
- Section 6 – “Standardized Approaches” describes the considerations involved in the design of standardized approaches to solvency assessment

Copyright © 2004 International Actuarial Association
• Section 7 – “Advanced Approaches” describes the considerations involved in the design of advanced or company-specific approaches to solvency assessment
• Section 8 – “Reinsurance” outlines the unique considerations involved with reinsurer solvency assessment
• Section 9 – “Total Company Requirement” describes the additional considerations involved in developing a combined approach to solvency assessment for an entire company or group of companies
• Appendix A – “Life Insurance Case Study” provides a life insurance numerical example of the most important elements of this report
• Appendix B – “Non-Life (P&C) Insurance Case Study” provides a non-life insurance numerical example of the most important elements of this report
• Appendix C – “Health Insurance Case Study” provides a health insurance numerical example of the most important elements of this report
• Appendix D – “Market Risk” provides an in-depth discussion of this risk as it affects insurers
• Appendix E – “Credit Risk” provides an in-depth discussion of this risk as it affects insurers
• Appendix F – “Lessons from Insurer Failures” provides insights from sample insurer failures
• Appendix G – “Introduction to Insurance Risk” provides a layman’s introduction to the risks faced by insurers
• Appendix H – “Analytic Methods” provide proven mathematical methods for estimating loss distributions
• Appendix I – “Copulas” describes the key features of these mathematical techniques for approximating risk dependencies
2. Executive Summary

2.1 This paper has been prepared for the International Association of Insurance Supervisors (IAIS) to explore the elements needed for an international capital standard for insurers and to provide a “best practices” approach available to all supervisors. It deals with methods the supervisor might use to assess the current financial position as well as to understand the range of possible future financial positions of insurers. Its primary focus is on capital requirements for insurers.

2.2 To assist in the development of a global framework for insurer solvency assessment and the determination of insurer capital requirements, the WP proposes a number of guiding principles to be used in their design. In summary, these principles focus on:

- A “three-pillar” approach to supervision (see Section 4.1)
- Principles versus rules-based approach (see Section 4.2)
- Total balance sheet approach (see Section 3.1.7 and 4.3)
- Degree of protection (see Section 3.1.5 and 4.4)
- Appropriate time horizon (see Section 3.1.6 and 4.5)
- Types of risks to be included (see Section 5.1.2, 5.1.3 and 5.2)
- Appropriate risk measures (see Section 4.5 and 5.3)
- Risk dependencies (see Section 6.2.1 and 9.3)
- Risk management (see Section 3.2.2)
- Standardized approaches (see Section 4.6 and 6)
- Advanced or company-specific models (see Section 4.6 and 7)
- Market efficient capital requirements (see Section 3.1.1)

“Three Pillar” Approach

2.3 The WP believes that a multi-pillar supervisory regime is essential for the successful implementation of the global framework proposed in this report. The conclusions of this report are consistent with the “three pillar” approach to the regulation of financial service entities that is reflected in the Basel Accord for the regulation of banks internationally.

2.4 The approach envisaged would have three pillars consisting of:

Pillar I: Minimum financial requirements
Pillar II: Supervisory review process
Pillar III: Measures to foster market discipline.

The definition of these pillars needs to reflect the specific features of insurance.

2.5 Pillar I (minimum financial requirements) involves the maintenance of a) appropriate technical provisions (policy liabilities), b) appropriate assets supporting those obligations and c) a minimum amount of capital (developed from a set of available and required capital elements) for each insurer. Of primary interest to the WP in this report are the capital requirements. To the greatest extent possible given the sophistication of the approach chosen and the insurer’s ability to model them, it is the WP’s view that these calculations must reflect a comprehensive view of the insurer’s own risks.
2.6 Pillar II (supervisory review process) is needed, in addition to the first pillar, since not all types of risk can be adequately assessed through solely quantitative measures. Even for those risks that can be assessed quantitatively, their determination for solvency purposes will require independent review by the supervisor or by a designated qualified party. This is especially true for those determined using internal models. The second pillar is intended to ensure not only that insurers have adequate capital to support all the risks in their business but also to encourage insurers to develop and use better risk management techniques reflective of the insurer’s risk profile and in monitoring and managing these risks. Such review will enable supervisory intervention if an insurer’s capital does not sufficiently buffer the risks.

2.7 Pillar III serves to strengthen market discipline by introducing disclosure requirements. It is expected that through these requirements, industry “best practices” will be fostered.

2.8 The actuarial profession can assist supervisors within the second pillar by providing independent peer review of the determination of policy liabilities, risk management, capital requirements, current financial position, future financial condition etc., where these entail the use of substantial judgement or discretion. Assistance can also be provided within the third pillar in the design of appropriate disclosure practices to serve the public interest.

2.9 The WP believes that while customization of the individual pillars is needed as they are applied to insurers, the use of a “three-pillar” approach similar to that used by the banks makes sense and is extremely useful given,

- the common features shared by the two financial sectors
- that many insurance supervisors are part of integrated financial supervisory agencies, and are well acquainted with the Basel Accord.

2.10 Some reasons for the differences in approach to be used for insurance would include 1) the nature of insurance risks and the techniques to assess them in Pillar I, 2) the need for multi-period review under Pillar II and 3) the definition of relevant information for purposes of disclosure in Pillar III.

**Principles Versus Rules-Based Approach**

2.11 Solvency assessment should be based on sound principles. Implementation of solvency assessment will require rules developed from these principles. However, the WP considers that the rules used should include provisions to allow their adaptation to current or unforeseen circumstances with the prior agreement of the relevant supervisor.

**Total Balance Sheet Approach**

2.12 The application of a common set of capital requirements will likely produce different views of insurer strength for each accounting system used because of the different ways accounting systems can define liability and asset values. In the view of the WP, these definitions may create a hidden surplus or deficit that must be appropriately recognized for the purpose of solvency assessment.

2.13 The WP believes that a proper assessment of an insurer’s true financial strength for solvency purposes requires appraisal of its total balance sheet on an integrated basis under a system that depends upon realistic values, consistent treatment of both assets and liabilities and does not generate a hidden surplus or deficit.
Degree of Protection

2.14 It is impossible for capital requirements, by themselves, to totally prevent failures. The establishment of extremely conservative capital requirements, well beyond economic capital levels, would have the impact of discouraging the deployment of insurer capital in the jurisdiction.

2.15 In forming its recommendation for an appropriate degree of protection for insurer solvency assessment purposes, the WP considered the role of rating agencies in assessing insurers and the substantial volume of credit rating and default data available from these agencies. The WP also noted the relation between the degree of protection and the time horizon considered. In addition, the specific manner of applying the capital requirement risk measure may also affect the degree of protection chosen. The WP’s recommendation for degree of protection is therefore linked with its recommendation for an appropriate time horizon for solvency assessment as shown in the following paragraphs.

Appropriate Time Horizon

2.16 A reasonable period for the solvency assessment time horizon, for purposes of determining an insurer’s current financial position (Pillar I capital requirements), is about one year. This assessment time horizon should not be confused with the need to consider, in such an assessment, the full term of all of the assets and obligations of the insurer.

2.17 The amount of required capital must be sufficient with a high level of confidence, such as 99%, to meet all obligations for the time horizon as well as the present value at the end of the time horizon of the remaining future obligations (e.g., best estimate value with a moderate level of confidence such as 75%).

2.18 Due to the long term and complex nature of some insurer risks, the insurer should consider valuing its risks for their lifetime using a series of consecutive one year tests with a very high level of confidence (say 99%) and reflecting management and policyholder behaviour (but no new business). Alternatively, this test can be conducted with a single equivalent, but lower (say 90% or 95%), level of confidence for the entire assessment time horizon. This lower level of confidence over a longer time horizon is consistent with the application of a series of consecutive higher level one-year measures.

Types of Risk Included

2.19 In principle, the WP recommends that all significant types of risk should be considered (implicitly or explicitly) in solvency assessment. However, there may be valid reasons why certain risks do not lend themselves to quantification and can only be supervised under Pillar II. The WP believes that the types of insurer risk to be addressed within a Pillar I set of capital requirements are underwriting, credit, market and operational risks.

Appropriate Risk Measures

2.20 A risk measure is a numeric indicator that can be used to determine the solvency capital requirement for an insurance company. The most appropriate risk measures for solvency assessment will exhibit a variety of desirable properties (e.g., consistency). Of course, it is difficult for one risk measure to adequately convey all the information needed for a particular risk. One risk measure that exhibits several desirable properties for various (but not all) risks is Tail Value at Risk (also called TVaR, TailVar, Conditional Tail Expectation, CTE or even Policyholders’ Expected Shortfall). In many situations, this risk measure is better suited to
insurance than Value at Risk (VaR), a risk measure commonly used in banking, since it is common in insurance for their risk event distributions to be skewed.

Risk Dependencies

2.21 The solvency assessment method should recognize the impact of risk dependencies, concentration and diversification. This has implications for the desirable properties of the appropriate risk measure.

2.22 Risk dependencies within an insurer can have a very significant impact on the overall net effect of its risks (compared to the gross effect without taking account of their dependencies). Even the most basic fixed-ratio method should implicitly allow for risk dependencies. Currently, required capital formulas in Japan and the U.S. incorporate some recognition of dependencies, concentration and diversification. However, in many countries, diversification between different risk types is not recognized in the formulas for required capital.

2.23 The concept of describing dependencies between risks, and particularly by using a technique based on copulas, is discussed in this report and its Appendices.

2.24 For purposes of solvency, it is imperative to find methods or models to describe dependencies both in the absence of reliable or scarce data as well as the “increasing” dependency in extreme events (i.e., in the tails of the probability distributions which describe the risks). The latter is very important to solvency assessment as the events in the tail of the distribution are those which can jeopardize the financial position of an enterprise most.

Risk Management

2.25 The solvency assessment method should recognize appropriately the impact of various risk transfer or risk sharing mechanisms used by the insurer.

2.26 The actuarial control cycle referred to in this report is a continuous review process that is fundamental to any soundly based enterprise risk monitoring process. The control cycle provides information to improve the company’s ability to manage its risks and make more effective business decisions. Some of the ways in which an insurer can manage its risks, beyond the fundamentals of prudent claim management, include

- risk reduction
- risk integration
- risk diversification
- risk hedging
- risk transfer
- risk disclosure

2.27 While many of these types of risk management serve to reduce the risk in question, it is important to note that some of them create additional risk related to the technique itself. For example, both hedging and reinsurance create counterparty risk, a form of credit risk.
2.28 Regardless of the risk management process used by the insurer for its risks, including full retention of its risks, effective management of these risks is encouraged by appropriate disclosure of the extent of the risks and their management by the company. Appropriate audiences for such disclosure include the stakeholders of the insurer including the supervisors.

**Standardized Approaches**

2.29 Many of the discussions comparing different solvency assessment methods (e.g., fixed-ratio versus risk-based capital - RBC - versus scenario-based, etc.) do not adequately explain the optimum conditions that must be present for each method to be reliable. Supervisors considering new methods should be alerted to the conditions needed for the new methods to be a success. The WP believes these concepts are worthy of note and appropriate inclusion in our report.

2.30 Simple risk measures are appropriate when it is recognized that the risk in question is important from a solvency perspective but there does not currently exist a generally accepted view of how the risk should be assessed. They are also appropriate if the risk is of minor importance.

2.31 Sophisticated risk measures are appropriate for material risks where one or more of the following conditions exist:

- The risk in question is very important from a solvency perspective and cannot be adequately assessed through the use of simple risk measures,
- There is sound technical theory for the risk to be assessed and the risk measure to be used,
- Sufficient technical skills and professionalism are present among the staff,
- Relevant and sufficient data is present or the knowledge about the risks is otherwise reliable,
- The risk is actually managed in accordance with the risk measure used,
- Risk management practices are evident to a high degree.

**Advanced (Company-Specific) Approaches**

2.32 For stronger, more technically able companies with effective risk management programs, it may be appropriate to introduce advanced (or company-specific) models that can incorporate all types of quantifiable risks. An internal model can also incorporate all types of interactions among risks if those interactions are understood and quantifiable. However, in practice, many aspects of risk are not well understood, particularly in the case of extreme events for which little history exists (and which are most important for solvency assessment). Hence, internal models provide a model of risks faced by an insurer that can, at best, be described as representing reality in an approximate way. In building an internal model, care must be given to capture the most important risk variables.

2.33 Required capital can be thought of as a second line of defence protecting an insurance company’s solvency and its policyholders. The first line of defence is solid risk management. If trouble develops that cannot be prevented through management of a risk, then capital should be available to cover the financial losses that emerge. It follows that in order for a supervisor to be content with a lower amount of required capital under a company-specific approach, there must be some assurance that the particular source of risk is under control, its effects are well mitigated and there is a reduced need for the required capital. Therefore, in approving a company’s use of an advanced or company-specific approach, the supervisor should confirm that the company has in place appropriate risk management processes together with a satisfactory reporting structure.
A particular strength of internal models is their ability to capture the impact of combinations of risks beyond a simple aggregation of individual risk factors that cannot accurately assess risk interaction effects.

**Market Efficient Capital Requirements**

Excessive minimum capital requirements, while affording additional solvency protection, will also serve to impede capital investment in insurers because of the perceived additional cost of capital required in the business, beyond that required by economic levels of capital, that may not be recoverable in product pricing.
3. Capital Requirements

3.1 The Purpose of Capital

3.1 In this report, the WP sets out a consistent framework for capital requirements and risk oversight for insurance companies that could be applied in almost all jurisdictions world-wide to suit the circumstances of each jurisdiction. Under this framework, the capital requirements and risk oversight process in two jurisdictions with similar business, legal, economic and demographic environments and supervisory philosophy and controls should be comparable. The resulting capital requirements may differ materially between jurisdictions that have significantly different environments for their insurance markets and companies. Nonetheless, because these requirements are based on a consistent set of principles, the differences between them should be explainable as a function of the different environments.

3.2 To set a target or requirement for the amount of capital and surplus that should be held by an insurance company requires a clear vision of the purposes for which capital is held. This then clarifies how the requirement should be determined. This section is devoted to reviewing the purpose of capital and the important principles for determining appropriate levels of capital.

3.3 An effectively defined capital requirement serves several purposes:
- provides a rainy day fund, so when bad things happen, there is money to cover them
- motivates a company to avoid undesirable levels of risk (from a policyholder perspective)
- promotes a risk measurement and management culture within a company, to the extent that the capital requirements are a function of actual economic risk
- provides a tool for supervisors to assume control of a failed or failing company
- alerts supervisors to emerging trends in the market
- ensures that the insurance portfolio of a troubled insurer can be transferred to another carrier with high certainty.

3.4 In developing capital requirements for insurers it is desirable to consider the concept not only of “target capital” (TC) but also “minimum capital” (MC). TC refers to the appropriate amount of capital to be held in consideration of the risks assumed by the insurer. MC serves as a final threshold requiring maximum supervisory measures in the event that it is breached. This Report focuses primarily on the issues surrounding the development of TC. Note that in this Report the WP uses the term “free surplus” (FS) to mean the financial statement excess of assets over liabilities and regulatory capital (TC) requirements.

3.1.1 Going Concern or Run-Off

3.5 Economic capital is what the firm judges it requires for ongoing operations and, for an insurance company, what it must hold in order to gain the necessary confidence of the marketplace, its policyholders, its investors and its supervisors. Economic capital can be considered to be the minimum amount of equity or investment to be maintained in the firm by its owners (shareholders) to ensure the ongoing operations of the firm. Since a firm’s net income is often measured as a rate of return on investor equity, many firms are motivated to maintain actual capital as close as possible to economic capital in order to maximize return on equity.

3.6 The WP is concerned not with economic capital but with target regulatory capital (i.e., TC), the capital that a firm is required by its supervisor to hold as a condition of being granted a licence or to continue to conduct the business of insurance in a jurisdiction. The focus in discussing regulatory capital is often placed on the sufficiency of capital to support the winding up of a firm’s affairs in the event of insolvency. From this point of view, regulatory capital is often thought of as providing for a successful run-off of the firm or a portfolio transfer. However, the firm before insolvency is a dynamic organization that is constantly changing. The capital that
would be needed in the event of insolvency depends on the company’s business portfolio immediately preceding the event of insolvency. In this sense, a regulatory capital requirement is based on the ongoing dynamic insurer’s business. Therefore, regulatory capital has aspects of both the going concern and run-off situations; it would be an error to characterize target regulatory capital as determined strictly on a going concern basis or strictly on a run-off basis.

3.7 Excessive capital requirements, while affording additional solvency protection, will also impede capital investment in insurers because the additional cost of capital may not be recoverable in product pricing. This either raises the cost of insurance to its buyers or prevents a market from existing.

3.1.2 Who and What is to be Protected

3.8 Providing protection to policyholders in the event of an insurer’s failure is a traditional justification for a regulatory capital requirement. In some jurisdictions, protection may be provided for general creditors of the insurance company as well. Creditors’ protection is not, however, a feature of many legal systems and will not be treated in depth in this report. Note that no consideration is given to the protection of the financial interests of the owners or shareholders of an insurer. In the case of a mutual insurance company whose owners are its policyholders, protection considerations apply only to these individuals as policyholders and not in respect of their roles as owners.

3.9 The type of protection to be provided to a policyholder in respect of an insurance or annuity contract will depend upon the terms of the contract and the nature of the insurance coverage.

3.10 Consider, for example, a typical short-term general (property and casualty) or group life or health insurance contract. If there were no incurred claims outstanding under the contract, the usual goal in an insurer’s failure would be to provide insurance coverage for the remaining term of the policy. It is assumed that the insured would then be able to arrange for a continuation of insurance with another insurance company. This assumption is generally valid because these contracts normally do not contain guarantees with respect to renewability or the level of renewal premiums. If claims have been incurred under a policy by the time the insurer has failed, the goal in a company failure would be to provide sufficient funds to satisfy the outstanding claims.

3.11 Longer-term insurance policies often involve predetermined premiums that are level for extended periods during the lifetime of the contract. Under these contracts, the year-by-year cost of insurance is not the same as the amount provided in the level premium to meet this cost. This leads to the creation of active policy liabilities or reserves that are held by the company to meet future insurance costs. In some jurisdictions, some portion of this liability may be represented concretely by guaranteed cash surrender values.

3.12 Certain insurance contracts, particularly life and health policies, guarantee the continuing coverage or protection of the insured (preservation of insurability). Since an insured’s condition may deteriorate over time, that individual might not be able to secure from another insurance company a continuation of insurance coverage in the event of failure of the primary insurer. For these contracts, in the event of insurer failure, supervisors or liquidators often seek to have these policies continued in force for their remaining terms.

3.1.3 Exit Strategy Under Failure

3.13 The method of liquidating a failed insurer is a principal consideration in determining regulatory capital. In many cases, the preferred method will be to have another insurer, or several insurers, assume the failed company’s insurance portfolio. In this case, the primary goal in setting a regulatory capital requirement is to ensure there will be sufficient assets on hand in the company’s estate so that another insurer will accept these assets as payment to assume the
business. In its work, the WP has assumed this is the course that would be followed in the event of an insurer’s failure.

3.14 There may be circumstances under which the policy liabilities are not transferred to or assumed by another insurer. This may be more likely in the event of a failure of a general (property and casualty) insurer than of a life insurer. In this case, the liquidator’s focus will be on the payment of incurred claims. The financial resources necessary to accomplish this will depend upon the organization established to run off this business. There can be considerable variation in the administrative costs of handling these claims. In setting capital requirements, a jurisdiction should not only provide for the amount of the claims on a failed insurer but it should also take into account the methods that would be used, and their associated costs, in settling these claims.

3.15 Many jurisdictions have consumer guarantee or compensation funds that protect policyholders in the event of failure of an insurance company. The coverage offered by the guarantee fund will usually have limits on benefits payable on a single contract. In some cases, these guarantee funds may be backed up by an organization that can assume the run-off of a failed insurer; this could have an important effect on the estimated costs of any future liquidation.

3.1.4 The Challenge of Insurer Solvency Assessment

3.16 Insurance contracts present unique challenges for solvency assessment. While insurers share a number of types of risk to which they are subject with other businesses, especially other financial institutions, their core risk is because of the fundamental nature of their business, the marketing and underwriting of risk. The types of risk to which insurers are subject, are detailed later in this report.

3.17 The proper assessment of underwriting risks usually requires the detailed examination of insurance product-specific and relevant industry data for both the frequency and severity of product events. The product events may involve the payment of specified amounts upon an event such as morbidity or death. They may also involve the reimbursement of specific types of costs whose amount will not be known until the insured service is actually provided (e.g., medical costs, property damage claims, etc.).

3.18 The assessment of underwriting risks for solvency purposes is challenging for several reasons:

- There is not a liquid market for many types of insurance contract liabilities.
- Insurable events can be subject to several types of assumptions (e.g., disability income claim payments require the estimation of the frequency and severity of claims as well as the rate of policyholder lapse, among other assumptions).
- Appropriate assumptions may be dependent on the experience of the insurer underwriting that risk. Such experience may not be available in sufficient detail or volume to fully estimate all aspects of the assumption with credibility without referring to relevant industry data, where this is available. In addition, the risk is dependent on the manner in which the risk was sold. Sometimes, one contract may be sold to many customers via various distribution channels, other times each customer may get a uniquely defined contract.
- Due to the long-term nature of many insurance contracts, the time horizon for projecting the future contract cash flows can extend for several years or even decades into the future thus making the estimation of assumptions challenging.
- For several types of life insurance products, the benefits available to the policyholder are dependent in some manner on the performance of assets purchased by the insurer. Risk assessment must be able to model the manner in which the insurer carries out its asset/liability management responsibilities.
• Frequently, the assessment of underwriting risk requires the modelling of policyholder behaviour (e.g., premium payment lapsation, the exercising of policyholder options).

• The long-term nature of many insurance contracts requires that the uncertainty and extreme event components of underwriting risk be carefully considered.

• Significant risk dependencies within an insurer’s risks need to be carefully considered in determining an appropriate solvency structure for insurers.

3.1.5 The Degree of Protection

3.19 The strength of a capital requirement can be thought of in terms of the probability that a company’s assets backing liabilities, together with required capital, will be sufficient to satisfy all of its obligations to its policyholders. This probability represents a confidence level. It would be desirable to be able to calculate this probability once the amount of capital was known or to know how much protection is provided by current capital and surplus. Conversely, an approach to determining required capital would be to first choose this confidence level and then determine the amount of capital necessary to achieve it. A difficulty with this approach is that some risks are not quantifiable, either because of their qualitative nature or because sufficient data is not available to properly assess the risk. Nonetheless, this is a promising approach that the WP believes can yield good results. In adopting this approach, it is important for supervisors in each jurisdiction to decide on the confidence level they believe is appropriate for the insurance companies supervised. Two practical considerations involved in the introduction of a new confidence level may be that: 1) if the new requirements are substantially higher than the previous ones; an appropriate transition period may be needed and 2) for some extreme circumstances (e.g., a steep fall in the investment market) a clear and transparent mechanism may be needed for the temporary relaxation of the solvency rules in order to avoid widespread hardship on the entire industry.

3.20 It must be recognized that the confidence level must be less than one (1) or 100%. No finite amount of capital can provide an absolute guarantee that a company’s policyholders will be protected in all circumstances. It is important to recognize that in any supervisory regime, no matter how strict, company failures will always be possible. This possibility cannot be eliminated through a high capital requirement.

3.1.6 Time Horizon

3.21 Financial statements, including reports on capital, are usually prepared by insurance companies at the end of each fiscal year or the end of each quarter year. Producing these statements is a considerable task that requires significant preparation time. Often there will be a delay of several months between the statement date and the actual receipt of the statement by the supervisory authority. The company management may also require some time to implement possible corrective actions. The supervisor, having many companies to oversee, may need several additional months to fully analyse a particular company’s results. If this analysis shows a company’s position to be weak, it will take additional time to formulate action plans and issue appropriate directions to the company. If it were necessary to remove a company’s licence and “wind it up,” the formalities of governmental and legal systems could introduce considerable delays before the supervisor’s objectives are achieved. During the period until final action against a weak or insolvent company is taken, the company would continue to operate and conduct business, including the sale of new insurance and/or annuity contracts.

3.22 In formulating a capital requirement in a particular jurisdiction, a supervisor must take into account the time horizon between the date as of which company financial statements are prepared and the expected date by which a supervisor could take control of the insurer if this was deemed to be necessary. Since this time horizon depends upon local business practices, the supervisor’s
resources, legislation and the legal system, this horizon will vary from one jurisdiction to another. However, it would be rare to assume this time horizon could be considerably shorter than one year.

**Term of Assets and Obligations**

3.23 This assessment time horizon should not be confused with the need to consider, in such an assessment, the full term of all of the assets and obligations of the insurer.

3.24 Regardless of the solvency assessment period time horizon (e.g., insurer’s assets must be adequate within a 99% probability that the insurer will still be solvent in one year), the solvency assessment must reflect the full term of the assets and obligations of the insurer. These may extend for many years or decades beyond the end of the assessment period time horizon.

**Period of Liquidation**

3.25 Since supervisory intervention in a nearly bankrupt company still requires a period of time to run-off, rehabilitate or sell off the company, it is necessary to consider this additional period of time. The solvency assessment time horizon should not be shorter than the expected length of time between the technical point of insolvency to wind-up or restructuring of the distressed insurer.

3.26 This period may be different for an insurer with business that is likely to be simply run-off versus an insurer whose business will be sold or restructured as a going-concern entity.

**Interaction with Confidence Level**

3.27 If a certain fixed acceptable level of insolvency risk per year is assumed (expressed as a certain allowable annual probability of insolvency), then extending the time horizon should always result in the need for additional capital. Alternatively, a fixed amount of capital always provides a lower confidence level in solvency over a longer period (e.g., higher probability of insolvency over the longer time horizon).

**Interaction with Modelling Behaviour**

3.28 Extending the time horizon will generally increase the need to make explicit assumptions on future policyholder as well as management behaviour, since a longer time horizon will increase the probability that current behaviour will change. In particular, the longer the time horizon, the more reasonable it seems to allow for:

   a. future transfers of risk (e.g., by changing the reinsurance policy or transferring the portfolio to another party); for instance, because of its size, this other party may not ask for capital to cover the remaining volatility risk;
   b. future changes of the company’s (re)investment strategy and/or internal risk management procedures, resulting in lower ALM risks and/or lower operational risks respectively;
   c. future offsetting risks because of new business that shows “opposite” types of risk.

3.29 In general, using a longer time horizon requires increasing judgement to be applied in the projections (i.e., larger model errors).
Future Financial Condition Reports

3.30 A longer solvency assessment time horizon may be useful where the purpose is to provide insight into the future financial condition of the insurer under a variety of plausible adverse scenarios. Some supervisors require that a multi-period future financial condition report be prepared annually for presentation to the insurer’s Board of Directors and a copy provided to the supervisor. Typically these reports are not publicly available because of the confidential nature of the information they contain.

3.1.7 Role of Accounting – The Need for a Total Balance Sheet Requirement

3.31 An insurer’s capital is determined from its financial statements as the difference between the value of its assets and liabilities. The strength of that capital value is directly dependent on the relative strength of the methods and assumptions used to determine the asset and liability values. The use of inconsistent methods and assumptions in the determination of asset and liability values (or between components within the assets and liabilities) has the potential to significantly affect the relative strength of the capital positions of otherwise similar insurers. Applying a common set of capital requirements will likely produce different views of insurer strength for each accounting system used because of the different ways that accounting systems can define liability and asset values. These definitions may create a hidden surplus or deficit. In the view of the WP, capital requirements generated under these systems must appropriately recognize these hidden values.

3.32 Ignoring for the time being, the different possible types of capital or surplus (retained earnings), the amount of capital attributed to a particular insurance company will depend heavily on how its policy liabilities (actuarial reserves) are calculated. The methods used to determine these reserves vary considerably among jurisdictions. In certain jurisdictions, conservatism and financial strength are emphasized; one often hears mention of “hidden surplus” contained within these reserves. In others, the emphasis is placed upon the appropriate reporting of earned income and actuarial reserves are considerably less conservative than in the first case. This variability demonstrates that in choosing a capital requirement, or in comparing capital amounts between companies, it is necessary to take into account the methods and assumptions used to determine all the components of the balance sheet including actuarial reserves.

3.33 The WP is aware of the work currently being done by the International Accounting Standards Board (IASB) to bring about a uniform international accounting standard for financial institutions. As part of this project, the IAA is assisting the IASB in determining a standard approach to actuarial principles and methods for the determination of actuarial reserves in accordance with the new standard. Initially, the WP viewed its mandate as the determination of a standard capital requirement based on a standard accounting system. However, since the timing of the completion of the IASB project is uncertain and the date of its adoption by all jurisdictions is not clear at this time, the WP has selected a “total balance sheet” approach (more on this in section 4.3) as a common basis for establishing capital requirements.

3.2 Supplements to Capital

3.34 Capital requirements can be thought of as a defence tactic used to protect policyholders and depositors. However, it is not the only tactic in use by insurance companies and by supervisors. The other defensive tactics that are in place will influence the amount of capital required by an insurance company. In this section, we describe some of these factors and indicate how they could enter into the design of a capital requirement.
3.2.1 Corporate Governance
3.35 The primary defence in preserving a company’s financial integrity is for the company to be well managed. There should be clear lines of responsibility and reporting and the company should have well-established and articulated operating rules and procedures. In summary, the company’s corporate governance is an important factor in preserving its well-being and its solvency. In setting Pillar II surplus target levels, the quality of a company’s corporate governance should be considered. If management or directors have less than optimal control of the company’s affairs, a higher than normal capital target level might be required. If the supervisor has not communicated corporate governance standards to supervised institutions and the overall level of corporate governance in the jurisdiction is not thought to be strong, it would be appropriate to reflect this in the design of a capital requirement.

3.2.2 Risk Management
3.36 A risk management program in an insurance company is an organized program in which sources and volumes of risk are tracked and procedures are in place to track and report on this risk. Important features of risk management include risk limits and risk management policies established by the board of directors, regular reporting of risk at the appropriate level in the company, and oversight by risk officers who are independent of business unit heads.
3.37 Risk management can be viewed as the first line of defence in a company or as a way to prevent the emergence of situations that could imperil the company. Capital supplements risk management; capital is required to support the financial costs to the company of situations where risk management is not a sufficient deterrent.
3.38 If the supervisor has confidence that a company’s risk management program is very sound and effective, it could be appropriate to reflect this in the calculation of required capital. This issue will be discussed in section 5.4 of this report.

3.2.3 Investment Policy and ALM
3.39 Since insurance companies usually pay policyholder benefits much later than the time at which premiums are received from policyholders, they must invest funds until these are required to pay claims. The investment income received from these assets is significant and is taken into account when premium rates are established. If investment income is insufficient or the value of invested assets declines significantly, an insurance company could experience significant difficulty.
3.40 Sound investment policies and a program of asset/liability management can significantly mitigate market, credit and mismatch risks. It would be appropriate for the design of a capital requirement to reflect the presence or absence of these risks and their effect on a company’s risk profile.
3.41 Certain investment risks can be controlled through a program of hedging. This involves the use of derivative securities. Hedging could be recognized in the design of a capital requirement. However, the supervisor would also want to consider the insurer’s hedging program, the availability of necessary financial instruments, the experience and abilities of company personnel engaged in this sophisticated activity and the company’s ability and success in conducting the hedging program.

3.2.4 Stress Testing
3.42 Regular stress testing can provide significant insight for company management into the risks faced by an insurer. Such stress testing has been introduced under various names (e.g., DST, DCAT, DFCA, DFA, etc.) in several jurisdictions. The method involves the construction of a computer model of an insurance company and the projection of all cash flows under a variety of scenarios of possible future experience. It is possible to study the effects on the company of the
future emergence of adverse experience and to measure the effects of various management strategies to deal with this experience.

3.43 Stress testing is a supplement to risk management. It does not replace a capital requirement but complements it. In a number of implementations, the object of the exercise is to verify that the company will be able to satisfy its regulatory capital requirements under a variety of future adverse scenarios. The WP is aware that the IAIS has prepared a paper on stress testing.

3.2.5 Risk Sharing and Participating Business

3.44 Certain insurance policies, most often life insurance, are sold as participating or with-profits business. These products feature participation by the insured in the profits of the business line through a system of policyholder dividends or bonuses. Other policies, such as Universal Life, contain adjustable or non-guaranteed elements that also allow the insurance company to adjust policy values, benefits or premiums in accordance with its experience with respect to these business lines.

3.45 An insurance company’s ability to pass unfavourable experience to its policyholders through the adjustment of dividends or policy values may be restricted. Restrictions can arise from a concept such as policyholders’ reasonable expectations (PRE) whereby policyholders may develop an expectation that various adjustable policy elements will continue to be administered by the insurer in accordance with past practices. For example, insurers may be reluctant to pass on the effects of unfavourable experience to policyholders for marketing reasons. PRE may be affected if changes to dividends or policy values are introduced with a considerable delay since the experience first began to deteriorate. Restrictions may also arise from contractual limits for certain policy elements (e.g., premiums, mortality and expense charges, interest crediting rates).

3.46 When considering capital requirements, the argument is often made that if risk is shared with policyholders through participation or adjustment of policy values, then lower capital requirements are appropriate for risk elements arising from this business. This argument has validity. However, in designing a capital requirement, the supervisor should consider the amount of credit that can be granted for risk pass-through features. A principal consideration is how the insurance company actually implements participation or adjustments. Significant capital relief should only be provided if the insurer passes unfavourable financial experience on to its policyholders without significant delay. The case may be slightly different depending on whether target capital (TC) or minimum capital (MC) is being considered. When defining the TC, fewer possibilities to transfer risks to policyholders might be appropriate than in the case of MC, which triggers maximum supervisory measures.

3.2.6 Actuarial Peer Review

3.47 Actuarial policy liabilities usually constitute the single largest item on the balance sheet of an insurance company. Therefore, the financial soundness of a company will often depend upon the quality of the actuarial work that was done to determine these liabilities. Independent peer review of a company actuary’s work (by an experienced reviewer) has been found in some jurisdictions to increase the quality of that work as well as the supervisor’s confidence in the company’s financial results. It has been used in these jurisdictions to enhance the supervisor’s confidence in the company’s financial results. These periodic actuarial peer reviews act in concert with capital requirements to enhance the protection of policyholders.
3.48 The actuarial profession can assist supervisors within the second pillar by providing independent peer review of the determination of policy liabilities, risk management, capital requirements, current financial position, future financial condition etc., where these entail the use of substantial judgement or discretion. Assistance can also be provided within the third pillar in the design of appropriate disclosure practices to serve the public interest.

3.2.7 Policyholder Protection Funds

3.49 Many jurisdictions have consumer protection or guarantee funds that (partially) compensate policyholders for losses incurred due to the failure of their insurance company. The question arises whether it would be appropriate to recognize the effect of these funds when designing a capital requirement. Recognition means that a company’s required capital is reduced since policyholders can be compensated by the fund. If this were done, financial responsibility would shift from the insurance company to those who pay for the fund, perhaps the government, but most often the entire insurance industry in the jurisdiction. This introduces a moral hazard issue since, in this situation, company management might be tempted to rely on the guarantee fund and to accept more risk than is appropriate for the company. The WP suggests that it is unwise to recognize guarantee funds within a capital requirement.

3.2.8 Supervisory Approach

3.50 The WP notes the crucial role played by insurance supervisors in fostering and maintaining an active and healthy insurance market within their jurisdiction. While the WP expresses no preference for one supervisory approach over another, we recognize the integral role played by supervisors along with other mechanisms (including capital requirements) which provide protection to insurance consumers. To the extent that global supervisory approaches differ then it will be difficult to construct a truly global framework for insurer solvency assessment and their attendant capital requirements.
4. Framework for Solvency Assessment

4.1 This section provides an introduction to the WP’s suggested framework for capital requirements for insurance companies. The fundamental principles underlying the framework are described first. This section also considers various implementation issues that will influence a supervisor in designing a local requirement. Section 5 describes the nature of insurer risks and appropriate risk measures. Section 6 suggests standardized approaches to capital that can be applied uniformly to all insurance companies in a particular jurisdiction. Section 7 describes more advanced and company-specific approaches to capital. The final sections of this report address the unique nature of reinsurer risks as well as capital considerations that apply to the company as a whole after all of its risks and its business operations have been considered separately.

4.2 Since the framework is necessarily general, to allow for a variety of circumstances in various jurisdictions, several case studies have been included in the appendices to this report to illustrate the application of the framework. Several technical supplements that discuss certain ideas in much greater depth than would be appropriate in the body of the report are also included in the appendices.

4.1 The Three Pillars

4.3 The Basel Committee on Banking Supervision (BCBS) has articulated an approach to banking supervision (known as the Basel II proposal) involving three pillars: Capital, Supervision and Market Disclosure. The approach is well known and, because of its consistent structure, appears, in principle, to be adaptable to and suitable for the supervision of other financial institutions, including insurance companies. The WP agrees with this approach and it has been used in our work.

4.4 While the WP’s task is to suggest a capital requirement framework for insurance companies, this might suggest that our work is mainly restricted to Pillar I. However, in considering the various risks that one would want to cover in a risk-based capital requirement, it has become apparent that there are several risks that are qualitative and not easily measured or quantified. Other risks are, in principle, quantifiable but not easily quantified since relevant data are not readily available and the appropriate models are not sufficiently developed at present. Since our approach to Pillar I is quantitative, these risks cannot be handled here. As does the BCBS, the WP suggests that these risks should be monitored by supervisors under Pillar II. While it might be appropriate for supervisors to increase the Pillar I capital requirements developed using our approach in consideration of these Pillar II risks, disclosure and corporate governance are also useful tools here as well. Suggestions concerning the treatment of these risks appear later in this report.

4.2 Fundamental Approach

4.5 The WP has assumed that the application by supervisors of the methods suggested herein would result in capital requirements that are consistent from one jurisdiction to another but are not necessarily identical. There are significant differences among jurisdictions in insurance products and markets, legal systems, accounting rules and population demographics that make it difficult to construct a universal capital requirement. Instead, the WP has sought to provide capital requirements that are both appropriate in individual jurisdictions and also consistent and comparable across jurisdictions.

4.6 To achieve our goal, we have sought to emphasize the basic principles that apply in each situation. It is only through an understanding of underlying principles that one can develop an appropriate treatment of various risks and aspects of the business of insurance.
4.7 Rules-based approaches to solvency assessment carry the advantage of simplicity of determination and of objectivity but can have the effect of encouraging insurers to “game the system” with respect to capital requirements, thus undermining the entire supervisory process. On the other hand, principles-based approaches focus on “doing the right thing.” These approaches tend to require more subjective judgement in their preparation and a different approach to supervisory review.

4.8 The WP suggests that solvency assessment should be based on sound principles. Implementation of solvency assessment will require rules developed from these principles. Rules should be adaptable to current circumstances.

4.9 There is great value from having capital requirements that are internationally consistent. The number of multinational companies that operate in a variety of jurisdictions is increasing. Consistent or uniform capital requirements are desirable so that competing domestic and international carriers are subject to similar requirements and fair competition is maintained in all domestic markets. Unfortunately, multinational insurers are now subject to some combination of the requirements of their home jurisdictions as well as the requirements of each foreign jurisdiction in which they do business. For example, prudential supervision in the European Union (EU) is based on the so called home country principle, which means that legal entities are supervised by the home country supervisors for all their business; the supervision by the host state supervisors is restricted to some emergency situations only. Hence, a subsidiary of a multinational insurer is supervised by authorities of the state in which the subsidiary is domiciled, but a branch is supervised by the authorities of the state where the insurer is domiciled. Uniform international solvency standards would facilitate co-operation between the foreign and home supervisors of an international company and could enable the foreign supervisor to place significant reliance on the work of a company’s home supervisor. In addition, fair competition and active insurance markets are encouraged when the requirements of the home and the foreign jurisdictions are consistent.

4.10 In particular, reinsurance is an international business. Both primary insurers and local supervisors require reassurance with respect to the financial strength of reinsurance companies who reinsure local business. A set of internationally consistent financial standards would greatly facilitate the understanding by all concerned of reinsurers’ financial strength. It would also help to prevent the arbitraging of capital between (and within) insurers and reinsurers operating in different jurisdictions.

4.11 While standards should be internationally consistent, they must recognize important national characteristics of the insurance industry. There are significant differences among jurisdictions in product design and in claims experience as well as in financial markets, including the supply and quality of financial assets available for insurance company investment; these must be taken into account by any local capital requirement. The treatment of asset related risks (in particular, credit risk and market risk) will depend upon the supply of available assets, the depth of local financial markets and the existence of measures of asset quality (perhaps as measured by rating agencies). Credibility of claims experience for establishing premiums, policy liabilities and capital requirements will depend upon the availability of local data. It would normally not be sufficient to use data from other jurisdictions. Such data normally are collected through inter-company studies carried out by the local industry association or by the local actuarial profession. The supervisor is urged to encourage the local industry and actuarial profession to create or expand industry-wide experience studies as a basis for establishing national valuation and capital requirements. The IAA will continue to foster the development of common international approaches in this regard.
4.12 Although the WP bases its work on principles in order to ensure universal applicability, the WP is aware that readers of this report would appreciate an illustration of how the report can be applied to arrive at concrete and explicit capital requirements. To this end, we have provided three case studies, for life, general (property and casualty) and health insurance. These case studies demonstrate how a capital requirement could be developed. The numbers contained in these case studies are for the purposes of illustration only and should not be taken as suggestions by the WP of explicit values that can be used in any local development of a capital requirement. The case studies are found in the appendices to this report.

4.3 Total Balance Sheet Approach

4.13 As described in the previous section, the application of a common set of capital requirements will likely produce different views of insurer strength for each accounting system used because of the different ways accounting systems can define liability and asset values. In the view of the WP, these definitions may create a hidden surplus or deficit which must be appropriately recognized for the purpose of solvency assessment.

4.14 The WP believes that a proper assessment of an insurer’s true financial strength for solvency purposes requires appraisal of its total balance sheet on an integrated basis under a system that depends upon realistic values, consistent treatment of both assets and liabilities and does not generate a hidden surplus or deficit.

4.15 In addressing the solvency question, the WP has attempted to separate the issues of accounting from the questions of solvency. Accounting determines the financial progress from period to period. As such it gives greater emphasis to the annual profit and loss statement than does prudential regulation. While positive financial progress can be a very good “leading indicator” of future solvency, prudential regulation focuses on the balance sheet (i.e., the capacity of insurers to meet their obligations to pay the present and future claims to policyholders). In order to separate out the accounting issues, the WP believes that solvency would be better defined in terms of a “total balance sheet requirement” (i.e., the sum of both the liabilities and the solvency capital requirement). Using the total balance sheet requirement (TBS) allows solvency assessment to be relatively independent of the accounting system (although factor-based approaches will still require use of verifiable accounting values). One obtains the (solvency) capital requirement as the difference between the TBS requirement and the liability requirement determined on the basis of the accounting system. This implies that if the accounting rules for assets or liabilities differ, the requirements for capital may differ as well.

4.16 The WP understands that the IASB aims to develop an insurer financial reporting system whereby the total balance sheet is valued on an integrated basis using realistic values. The use of such a financial reporting system is intended to help readers of the financial statements to understand directly the elements of conservatism inherent in the financial statements. Equally, such an approach should enable insurer capital requirements to be better coordinated with the protection afforded within the policy liabilities (e.g., technical provisions or reserves).

4.17 However, since there is currently no international uniformity in accounting systems used by the insurance industry, the development of a global framework for insurer solvency assessment based on these current accounting systems is impossible. The WP has selected the TBS approach since it offers the most promise as the foundation for such a global framework. The TBS approach is relatively independent of the accounting system. Of course, standardized factor-based approaches will require use of verifiable accounting values and the degree of conservatism contained in these values should be taken into consideration as part of their determination.
4.4 Degree of Protection

4.18 As was discussed earlier in section 3.1.5 of this report, it is impossible for capital requirements, by themselves, to totally prevent failures. The establishment of extremely conservative capital requirements, well beyond economic capital levels, will have the impact of discouraging the deployment of insurer capital in the jurisdiction.

4.19 The WP considered the role of rating agencies in assessing insurers and the substantial volume of credit rating and default data available from these agencies. This data is helpful in identifying the rating classes that are indicative of insurers in difficulty. Further, the data is suggestive of the cumulative probability of default, over various time horizons, for different current ratings. The WP does not believe it is possible to directly link the solvency degree of protection to these ratings for a variety of reasons (e.g., different rating agency methodologies, different current credit ratings of insurers, etc.) but this information was helpful to the WP in forming its views on this matter.

4.20 As mentioned earlier in section 3.1.5, the degree of protection afforded by a set of capital requirements is dependent on the time horizon considered. In addition, as shown in section 4.5, the specific manner of applying the capital requirement risk measure may also affect the degree of protection chosen. The WP’s recommendation for degree of protection is shown in section 4.5.

4.5 Time Horizon

4.21 As was discussed earlier in section 3.1.6 of this report, it is inevitable that there will be some time delay between the date the supervisor can take appropriate action with respect to an unacceptably weak or insolvent insurer and the date the published financial statements of the insurer are produced. During this period, it is likely that the company would continue operations. Therefore, a capital requirement must also provide for the company’s business written during this time as well as being sufficient with respect to the existing business as of the statement calculation date.

Uncertainty

4.22 It is generally agreed that uncertainty risks (e.g., regarding the future levels of the best estimate mortality) must be considered for the full remaining term of the insurance contracts.

Volatility

4.23 On the other hand, some argue that volatility risks can be ignored in the long run, since these risks may be diversified away in the future (note that this is not universally true – some elements of volatility risk cannot be diversified away). It is argued that the greater danger to solvency from the volatility component of risk may result not from long run exposure but rather the ability to withstand short-term volatility, perhaps within a one-year time frame.

4.24 This suggests that the choice of the time horizon per risk should depend on the issue of whether the risk at hand could be considered as “systematic” or “diversifiable.” However, the WP has strong doubts whether all types of risks can clearly be classified into one of these two categories in practice. Many types of risks may have both systematic and diversifiable components. Moreover, this distinction may also depend on the size of the company and the character of the market(s) in which it operates.

---

1 The same doubts have been expressed in Section 5 of the IASB Draft Statements of Principles on Fair Value accounting.

Copyright © 2004 International Actuarial Association
Extreme Events

4.25 The solvency assessment time horizon should be long enough to capture the impact of extreme events, should they occur, and all associated ripple or tail correlation effects associated with the extreme events.

Recommendation

4.26 In consideration of the above elements of discussion, the WP is of the view that a reasonable period for the solvency assessment time horizon, for purposes of determining an insurer’s current financial position (Pillar I capital requirements), is about one year. This assessment time horizon should not be confused with the need to consider, in such an assessment, the full term of the assets and obligations of the insurer.

4.27 The amount of required capital must be sufficient with a high level of confidence, such as 99%, to meet all obligations for the time horizon as well as the present value at the end of the time horizon of the remaining future obligations (e.g., best estimate value with a moderate level of confidence such as 75%).

4.28 Due to the long term and complex nature of some insurer risks, the insurer should consider valuing its risks for their lifetime using a series of consecutive one year tests with a very high level of confidence (say 99%) and reflecting management and policyholder behaviour (but no new business). Alternatively, this test can be conducted with a single equivalent, but lower (say 90% or 95%), level of confidence for the entire assessment time horizon. This lower level of confidence over a longer time horizon is consistent with the application of a series of consecutive higher level one-year measures.

4.29 The assessment of an insurer’s future financial position under Pillar II according to various adverse scenarios might reasonably include projected future financial positions for five years for life insurance and two years for general insurance.

4.6 Standardized and Advanced Approaches

4.30 The WP has considered a variety of approaches for determining a capital requirement. The optimal approach would result in a requirement that is determined separately for each insurance company so as to produce a capital value most appropriate for that company. The result of this approach would be a calculation of the company’s economic capital. However, this approach can be labour intensive and may require a degree of technical sophistication that may be beyond many companies’ abilities and resources even though it directly aligns the management of a company’s risks with its measurement process.

4.31 It is more practical to begin from the other end of the spectrum with a standardized approach. Under a standardized approach, capital would be determined using the same calculations for all companies in a jurisdiction. For each source of risk, a standardized measure of a company’s exposure to that risk would be multiplied by a standardized factor determined for the jurisdiction as a whole. The factors would be calculated to reflect the circumstances of the jurisdiction. Since this approach is meant to determine a minimum value for capital for all companies licensed to conduct business, the factors would be expected to be fairly conservative. Nevertheless, the standardized approach should not be in clear contradiction with the principles of economic capital and it needs to be applied thoughtfully to ensure that the factors do not lead to inadequate risk measurement processes within the company. The various sources of risk and methods of determining the factors required for them are described later in this report. A complete discussion of the standardized approach is contained in section 6.
For stronger, more technically able companies with effective risk management programs, it may be appropriate to introduce alternate methods for determining the capital required with respect to specific risks. There is a wide variety of possible alternate methods. These range from the use of company-specific risk factors based upon company experience to alternate calculation methods and to the use of risk and cash flow projection internal models. In general, methods that are more tailored to the circumstances of an individual company would be expected to produce lower capital requirements than would be calculated using the standardized approach. This is due to the conservative bias in the standardized factors, required by the need for the standardized approach to apply to all companies. Low capital requirements could be acceptable to the supervisor if there was assurance that the resulting capital value was appropriate and the insurance company had in place very strong risk management and controls. Advanced methods, including internal models, are currently in use within the insurance capital regimes in Canada and Australia. They are also used under the current Basel Capital Accord to determine the capital for market risk in banks’ trading books of assets. Advanced approaches are discussed in section 7 of this report.

### 4.7 Total Company Approach

The WP’s risk-based approach to required capital treats each source of risk separately. Initial capital amounts are determined for each of them. However, the task does not end with these calculations. There are numerous reasons why the proper capital requirement for a company is not the simple sum of the requirements calculated in respect of each of the risks to which it is subject.

Adjustments to the simple sum of individual risk-based capital amounts may be required because of concentration of risks, diversification of risks, or dependencies among risks. The concept of correlation between risks is often introduced in connection with these elements.

The WP suggests that a company’s total capital requirement should recognize the relationships among the various sources of risk that can affect its operations. Therefore, the simple sum of individual risk-based components should be adjusted appropriately. This topic is discussed more fully in sections 6-8.

### 4.8 Implementation Issues

There are many requirements for the introduction of a detailed risk-based solvency system for the supervision of insurance companies. Many of these, such as the legal framework, the accounting framework, and the business environment are outside the scope of the WP’s charge. The WP understands that the IAIS has prepared and continues to develop guidance on these and related matters. There are, however, a number of practical implementation issues upon which the WP offers comment.

#### 4.8.1 Data

Determining numerical factors in the standardized approach, or alternate methods in the advanced approaches, will be based upon extensive data covering the experience of the insurance industry in the local jurisdiction. Some of this data may have been collected by the supervisor through regular filings of required information. Other necessary data may have been collected by the industry trade associations. In many jurisdictions, the actuarial profession conducts regular inter-company studies of industry experience under insurance policies. Experience shows, however, that it may be necessary to conduct special-purpose data collection exercises for the purpose of calibrating a capital requirement. This can be a difficult though necessary undertaking that requires considerable planning.
4.8.2 Rating Agencies

4.38 Assessing credit risk with respect to specific assets usually involves consideration of the rating assigned to an asset by a leading rating agency. The WP recognizes that rating agencies may not operate in or cover the assets of all jurisdictions. If agency ratings are not available, the supervisor will require an effective local substitute.

4.8.3 Availability of Qualified Professionals

4.39 Determining a capital requirement, as well as assessing the results when this requirement is applied to the insurance industry, is a technically sophisticated matter requiring the skills of trained professionals, including actuaries. Supervisors may have the necessary personnel on their own staff. Supervisors may be able to recruit assistance from the local professional body or industry, or they could use the services of consultants, local or foreign. It is important that those who undertake to determine the details of a risk-based capital requirement have a sufficient knowledge of risk, statistics, finance and business.

4.9 Available Capital

4.40 A capital requirement is used to specify a minimum amount of capital that an insurance company must have. However, a statutory capital standard would be incomplete unless it specified what capital instruments a company could use to satisfy the requirement. This is the question of available capital.

4.41 The WP notes that the IAIS is currently developing guidance on available capital. Our understanding is that this guidance will use a tiered structure similar to that in the Basel Capital Accord. While the WP endorses convergence in this regard, careful consideration may need to be given to unique aspects of the insurance business which may require some modification of the banking approach.
5. Insurer Risks

5.1 Risk Fundamentals

5.1 The overall management of an insurer includes:

- the design, pricing, marketing and underwriting of its insurance policies;
- the selection of assets backing the policies;
- the estimation of the size and volatility of the liabilities associated with those policies;
- the determination of the insurer’s capital needs;
- claims management;
- the updating of all these elements over time as more data and other information becomes available or because the underlying risk processes change;
- an adequate/sound disclosure/communication process to key stakeholders (e.g., management, supervisors, policyholders and investors);
- future financial condition analysis which provides a prospective multi-scenario view of the company as a whole.

5.2 These steps in the overall management of an insurer are illustrated in the following diagram, similar to the one used by the Australian Institute of Actuaries to describe the “actuarial control cycle.” The diagram illustrates that the operations of an insurer are bounded by the business environment in which it operates (e.g., legal, social, competitive, client, economic, governmental, tax, etc.) as well as the professionalism of all its employees.

![Diagram of Insurer Risks and Operations](image-url)
5.3 Risk is inherent in each of steps pictured in the diagram. The assessment of these risks is key to the operations of an insurer. Since actuaries specialize in the financial measurement and management of risk and contingent events, it is natural that actuaries can be of assistance in the assessment of risk, at many points of the “actuarial control cycle.”

5.4 It is important to note the central role of capital in the above diagram. Capital represents an essential buffer to ensure that policyholder obligations can be met. The operations of an insurer, after the net effect of all their inherent risks, must yield a rate of return deemed reasonable by the providers of the insurer’s capital. If additional capital is required, beyond that needed for all of the appropriate risk factors at an adequate level of confidence (e.g., 99% confidence level), then (in an efficient market) less capital will be attracted to the insurance sector if the insurance products cannot be priced to recover the additional cost of capital. On the other hand, insufficient requirements, in comparison with that deemed necessary by modelling all of the appropriate risk factors at an adequate level of confidence, may result in inadequate pricing and will increase the exposure of the insurer, over time, to the risk of insolvency.

5.1.1 Definition of Risk

5.5 Throughout this report reference is made to risk. Because of its importance to this report, it is useful to understand clearly the definition of risk. There are many different definitions of risk but a useful one was published in 1995 by Standards Australia and Standards New Zealand when they released a Standard on Risk Management (ASNZS 4360:1995). Included in that Standard is the following definition of risk.

“Risk – the chance of something happening that will have an impact upon objectives. It is measured in terms of consequences and likelihood.”

5.6 This definition implies that risk may entail both upside as well as downside impacts. This concept is reinforced later in the Standard.

“Risk management is as much about identifying opportunities as avoiding or mitigating losses.”

5.7 Risk only has meaning in the context of a set of objectives or expected results. For example, we might expect the value of automobile insurance claims from a given portfolio of business to be a certain amount. In reality, the actual amount of claims may differ because of the presence of various risks. Appendix G contains a high-level layperson’s example of the importance of risk to an insurer.

5.1.2 Introduction to Insurer Risk Types

5.8 While the WP recognizes that insurer risks include many internal dependencies that require an integrated approach to risk or solvency assessment, the WP suggests that insurer risks be categorized under four major headings:

- Underwriting
- Credit
- Market
- Operational

5.9 While each risk is listed as if it existed in isolation, independent of the other risks, there are situations, as occurs in life insurance, where products are specifically designed and then managed with the asset and liability risks modelled together in an integrated fashion. In addition, there are other important considerations for combining the impact of the various risks across the whole company. The “Sharma” report, commissioned by the EU insurance supervisors, studied a number of insurance company failures or near failures and concluded that the final cause for a
failure is always a realization of some concrete risk, but in most cases the real cause is much earlier and more abstract. The “Sharma” report introduced the concept of a “causal chain” of events leading to failure.

5.10 Specific insurance risks that are covered by the company through the insurance contracts it sells are specifically identified as underwriting risks. The other risks are generally present (to different degrees) in other financial institutions. For example, market risk is generally associated with changes in the values of invested assets.

5.11 The WP recommends that capital requirements against asset related risks (e.g., credit and market risks) need not be determined for free assets, those assets which are not supporting the liabilities or the capital requirements themselves. The imposition of capital requirements on these free assets discourages insurers from maintaining more capital than absolutely necessary in the insurer. The imposition of such requirements is therefore counterproductive in enhancing the protection of policyholders.

5.12 The WP notes that liquidity risk is frequently associated with the sale of assets, although the underlying cause of a liquidity situation may not be due solely to market risk. The WP recommends that liquidity risk be addressed within Pillar II rather than Pillar I capital requirements (see appendix D for additional commentary).

5.13 The WP uses the common definition of “operational risk” which includes non-underwriting risk losses internal to the insurer (over which the insurer may have significant control) as well as those that are caused by external non-underwriting risk events (i.e., “event” risks over which the insurer may have little control). The WP recommends that operational risk be eventually addressed, at least partially, within Pillar I capital requirements.

5.14 Each major category contains several more specific risks, which are described in more detail, later in this section.

5.1.3 Key Components of Risk

5.15 In modelling risk, actuaries pay special attention to the following key components of risk for each peril. The modelling tools described later will need to reflect the following components of risk resulting from each peril.

Volatility

5.16 Volatility is the risk of random fluctuations in either the frequency or severity of a contingent event, such as the risk that the rolling of one die will be different from its expected (or average) result of 3.5. This risk is “diversifiable,” meaning that the volatility of the average claim amount declines as the block of independent insured risks (or the number of rolls of the die) increases.

5.17 In fully efficient markets, volatility would not be valued in the calculation of the fair value of a set of projected future cash flows. Only capital would be used to absorb the fluctuations arising from volatility risk. This efficient market pricing theory is based on an investor’s point of view, whereby the risks in their own portfolio can be diversified. However, because of the relatively inefficient markets for valuing insurance risks, the volatility component of risk cannot be ignored, since policyholders usually cannot diversify that risk away. An insurer can go into bankruptcy because of diversifiable risk and the policyholders should be protected against that risk.
Uncertainty

5.18 Uncertainty is the risk that the models used to estimate the claims or other relevant processes are misspecified or that the parameters within the models are misestimated. Uncertainty risk is non-diversifiable since it cannot be (relatively) reduced by increasing portfolio size.

5.19 Using the die example above, if the die actually has two 5’s on it and no 6 (or a different number of sides), then the estimate of 3.5 based on a “normal” die has misspecified the expected value. Since insurance companies often have unique underwriting standards and market niches, they may be expected to have their own unique parameters. Thus, actual experience observed for one group may not be indicative of the future experience for another group and the experience of the whole population may not be appropriate for an individual company.

5.20 Included in uncertainty are three key elements:

1. The model itself may be incorrect (i.e., no parameters may exist that make the model an adequate description of reality). This is usually referred to as “model error” risk. This can occur when the distribution itself is misunderstood (such as the actual process may be lognormal and one assumes it is normally distributed) or when a key driver or relationship is wrong. However, this introduction of model error may be a deliberate choice in order to have a simpler, more usable model, with an acceptable error tolerance.

2. Even if the model of a cash-flow process is correct, and the underlying model is appropriate, the parameters need to be estimated. Parameter risk is the error in this estimation, which exists because
   - the number of observations on which best estimates are based is limited because the observation period is too short
   - the volatility of the observations makes estimation less certain
   - the period over which the observations were made may not include certain calamitous events that, in fact, should be reflected in the parameters of the distribution
   - the observations contain contaminated data.

3. In addition, the risk structure (i.e., parameters) can change over time or be uncertain for other reasons. This too needs to be considered in modelling the risks. Sometimes called structural risk, examples of this include a new court ruling that changes the interpretation of policy language, a new medical breakthrough (cure for cancer), or a new disease (AIDS). This risk is sometimes incorporated into the model through “structural” distributions of parameters.

5.21 For example, all of these uncertainty elements contribute to estimating the likelihood of an earthquake in the New Madrid area of the United States (St. Louis to Memphis along the Mississippi River). A significant uncertainty relates to whether such an earthquake is a 1 in 100-year event or a 1 in 1,000 or higher year event.

Extreme Events

5.22 Extreme events have also been described as high-impact, low-frequency events for the company as a whole. For any risk, one or more extreme events can cause fluctuations to be much greater than might be expected to arise from normal (modelled) fluctuations under items 1 or 2 above. These are one-time shocks from the extreme, adverse tail of the probability distribution that are not adequately represented by extrapolation from more common events and for which it is usually difficult to specify a loss value, and thus an amount of capital to hold. For example, a contagious disease process may affect many persons simultaneously, nullifying the usual assumption of independence among persons; or, a rumour or dramatic public statement might lead to a severe liquidity shortfall scenario at an insurance company. Another possibility is that an event occurs
which has an extremely low probability of occurrence. Using the dice example again, there would be a very low chance that two dice end up leaning against each other with no clear result of the roll.

5.23 The risk of extreme events, beyond normal volatility of cash flows, needs special consideration since the resulting fluctuations may be so extreme as to require independent management strategies.

5.2 Types of Risks

5.2.1 Underwriting Risk

5.24 Insurance companies assume risk through the insurance contracts they underwrite. The risks within the underwriting risk category are associated with both the perils covered by the specific line of insurance (fire, death, motor accident, windstorm, earthquake, etc.) and with the specific processes associated with the conduct of the insurance business. The WP has chosen not to list all the specific hazards, but rather to focus on more generic risks that apply to all (or at least many) lines of insurance:

- Underwriting Process Risk- risk from exposure to financial losses related to the selection and approval of risks to be insured
- Pricing Risk- risk that the prices charged by the company for insurance contracts will be ultimately inadequate to support the future obligations arising from those contracts
- Product Design Risk- risk that the company faces risk exposure under its insurance contracts that were unanticipated in the design and pricing of the insurance contract
- Claims Risk (for each peril)- risk that many more claims occur than expected or that some claims that occur are much larger than expected claims resulting in unexpected losses. This includes both the risk that a claim may occur, as well as the risk that the claim might develop adversely after it occurs
- Economic Environment Risk- risk that social conditions will change in a manner that has an adverse effect on the company
- Net Retention Risk- risk that higher retention of insurance loss exposures results in losses due to catastrophic or concentrated claims experience
- Policyholder Behaviour Risk- risk that the insurance company’s policyholders will act in ways that are unanticipated and have an adverse effect on the company
- Reserving Risk – risk that the provisions held in the insurer’s financial statements for its policyholder obligations (also “claim liabilities,” “loss reserves” or “technical provisions”) will prove to be inadequate.

5.25 Appendices A, B and C of this report provide detailed descriptions of the considerations involved in assessing underwriting risk in life, non-life and health insurers through case studies.

5.2.2 Credit Risk

5.26 Credit risk is the risk of default and change in the credit quality of issuers of securities (in the company’s investment portfolio), counter-parties (e.g., on reinsurance contracts, derivative contracts or deposits given) and intermediaries, to whom the company has an exposure. Within this category, we include:
• Direct Default Risk - risk that a firm will not receive the cash flows or assets to which it is entitled because a party with which the firm has a bilateral contract defaults on one or more obligations
• Downgrade or Migration Risk - risk that changes in the possibility of a future default by an obligor will adversely affect the present value of the contract with the obligor today
• Indirect Credit or Spread Risk - risk due to market perception of increased risk (i.e., perhaps because of the business cycle or perceived credit worthiness in relation to other market participants)
• Settlement Risk - risk arising from the lag between the value and settlement dates of securities transactions
• Sovereign Risk - risk of exposure to losses due to the decreasing value of foreign assets or increasing value of obligations denominated in foreign currencies
• Concentration Risk - risk of increased exposure to losses due to concentration of investments in a geographical area or other economic sector
• Counterparty Risk - risk of changes in values of reinsurance, contingent assets and liabilities (i.e., such as swaps that are not otherwise reflected in the balance sheet).

5.27 The table below relates market and credit risks of an insurer to the business segments where they are manifest.

<table>
<thead>
<tr>
<th>Insurer Market &amp; credit risks (IR=Interest Rate risk; FX=Foreign Exchange risk)</th>
<th>Invested assets</th>
<th>Insurance contract liabilities</th>
</tr>

</table>

Dependencies should be considered. Example: dependency between market shocks and credit risk.

5.28 Appendix E of this report provides a detailed description of the considerations involved in assessing credit risk for insurers.
5.2.3 Market Risk

5.29 Market risk arises from the level or volatility of market prices of assets. Market risk involves the exposure to movements in the level of financial variables such as stock prices, interest rates, exchange rates or commodity prices. It also includes the exposure of options to movements in the underlying asset price. Market risk also involves the exposure to other unanticipated movements in financial variables or to movements in the actual or implied volatility of asset prices and options. Within this category, are included:

- Interest Rate Risk - risk of exposure to losses resulting from fluctuations in interest rates
- Equity and Property Risk - risk of exposure to losses resulting from fluctuation of market values of equities and other assets
- Currency Risk - risk that relative changes in currency values decrease values of foreign assets or increase the value of obligations denominated in foreign currencies
- Basis Risk - risk that yields on instruments of varying credit quality, liquidity, and maturity do not move together, thus exposing the company to market value variation that is independent of liability values
- Reinvestment Risk - risk that the returns on funds to be reinvested will fall below anticipated levels
- Concentration Risk - risk of increased exposure to losses due to concentration of investments in a geographical area or other economic sector
- Asset/Liability Mismatch Risk – to the extent that the timing or amount of the cash flows from the assets supporting the liabilities and the liability cash flows are different (or can draft apart) the insurer is subject to asset/liability mismatch risk
- Off-Balance Sheet Risk - risk of changes in values of contingent assets and liabilities such as swaps that are not otherwise reflected in the balance sheet.

5.30 Appendix D of this report provides a detailed description of the considerations involved in assessing market risk for insurers.

5.2.4 Operational Risk

5.31 The concept of operational risk has primarily emerged from the banking industry, and initially was defined in complementary terms, namely all risks other than market or credit. The Basel Committee on Banking Supervision (BCBS) has proposed a capital requirement for operational risk for banking institutions. In order to evaluate a capital requirement specific risks need to be identified and measured and this has led to the adoption of the definition that was initially developed by the British Banker’s Association. Operational risk, for capital purposes, is defined as “the risk of loss resulting from inadequate or failed internal processes, people, systems or from external events”.

5.32 The above definition is intended to include legal risks but exclude strategic, reputational and systemic risk.

5.33 In the banking industry thousands of transactions are processed each day. Therefore, the amount of data in respect of losses arising from operational failures is more abundant. This naturally lends itself to the development of frequency and severity models to evaluate the aggregate loss distribution and hence the capital requirement.

5.34 In the banking sector it is believed that credit accounts for 60% of all risk, operational risk is 30%, market risk is 5% and other risks represent the remaining 5%.
5.35 The Bank for International Settlements (BIS) has used Quantitative Impact Studies (QIS’s) to gather operational risk experience. There appears to be insufficient data of the right type for a Pillar I requirement under Basel II at the present time.

5.36 The BIS will likely not increase the overall Pillar I target standard capital ratio of 8% to allow for operational risk since there is some belief that operational risk is already implicitly provided for in the setting of the 8% target standard ratio.

5.37 It appears likely that Basel II will require operational risk assessment within Pillar I. Banks will be offered the choice of “basic indicator”, “standardized” and “advanced measurement approaches”. Many banking supervisors require their banks to hold additional capital above Pillar I levels because of Pillar II issues.

5.38 Operational risk is also an important risk for insurers and it should be provided for in a multi-pillar supervisory framework. Operational risk has been recognized as an important risk for insurers as well as for banks (EU Supervisory “London Group” produced the Sharma Report that indicated management shortfalls led to many EU insurer failures).

5.39 However, because of the current general lack of sufficient insurer quantitative data (i.e., operational risk data gathering is less advanced than in the banks; nature of operational risk in insurers differs from that in banks because of the different nature of the businesses), there can be no experience-based explicit Pillar I requirement for insurers at this time. In the interim, a non-experience-based Pillar I requirement can be used but the WP recommends it be accompanied by incentives for companies to demonstrate sound operational risk management.

5.40 Due to the importance of operational risk in the causal chain of events leading to insolvency, the WP recommends that operational risk for insurers be addressed in Pillar I. It may be reasonable to offer a Basel II type of approach with a choice of a “basic indicator”, “standardized” and “advanced measurement approach.”

5.41 A challenge for insurers in assessing operational risk is to separate this risk from the loss experience data typically collected for the other underwriting, credit and market risks. For example, insurers will need to examine the portion of their “underwriting losses” that are really due to ineffective or faulty underwriting processes or client management.

5.42 It is recommended that insurance supervisors, the insurance industry and the actuarial profession work together to develop appropriate research to measure operational risk.

5.2.5 Liquidity Risk

5.43 Liquidity risk is inherent in the financial services industry. In an insurance context, liquidity risk is exposure to loss in the event that insufficient liquid assets will be available, from among the assets supporting the policy obligations, to meet the cash flow requirements of the policyholder obligations when they are due. In more general terms used in the financial industry, liquidity risk within insurance companies is called funding liquidity risk, as opposed to trading related liquidity risk that banking institutions face raising necessary cash to roll over their debt or to meet cash, margin or collateral requirements. An insurer should be aware of the potential liquidity risks associated with the early termination of insurance contracts. Losses due to liquidity risk can occur when a company has to borrow unexpectedly or sell assets for an unanticipated low price. The liquidity profile of a company is a function of both its assets and liabilities.
5.44 Life insurers often offer policyholders embedded options (e.g., settlement options) that have the potential to cause liquidity problems. General insurers occasionally have to pay claim settlements earlier than expected, thereby being required to liquidate invested assets prematurely or at unfavourable terms.

5.45 There are different levels of liquidity management:
- Day-to-day cash management, which is commonly a Treasury function within a company
- Ongoing cash flow management, which typically monitors cash needs for the next six to twenty-four months.
- Stress liquidity risk, which is focused on catastrophic risk.

5.46 It is important to recognize that stress liquidity risk management is distinct from asset/liability management and capital management issues. It is therefore not generally covered by actuarial opinions and may not be included in normal measures of risk-based capital; rather, it is a separate and fundamental area of financial risk management.

**Possible Sources of Liquidity Risk**

5.47 Unexpected demand for liquidity may be triggered by,
- cash calls following major loss events
- a credit rating downgrade
- negative publicity, whether justified or not
- deterioration of the economy
- reports of problems of other companies in the same or similar lines of business
- extent of reliance on and performance of secured sources of funding and their terms (e.g., line of credit capacity and conditions)
- breadth of funding and accessibility/liquidity of capital markets (e.g., through catastrophe bonds).

5.48 Other random fluctuations in demand for liquidity and certain company-specific characteristics can amplify liquidity risk. However, these characteristics by themselves may or may not cause liquidity failure. Good liquidity management can significantly reduce that risk. Examples of company-specific characteristics that can contribute to liquidity risk exposure include:
- A single contract holder or a few contract holders who control large sums of money (policies or contracts). Institutional-type products are the biggest risk in this respect, although in retail lines, a small group of agents and/or brokers may control large blocks of business, and they pose a similar risk.

---

2 The most striking example of loss due to this risk is a “run-on-the-bank” event that causes an institution to fail. This type of event hit banks during the Depression when too many customers demanded to have their money paid immediately in cash, and the demand exceeded the cash reserves. An illustration of the liquidity risk problems which can occur in the insurance industry, occurred on July 30, 1999, when an American insurer’s credit rating was downgraded by a major rating service company. In the days following the downgrade, many investors invoked the seven-day redemption clause in the short-term funding agreements issued by the insurer. The funding agreements suddenly behaved like short-term liabilities despite the fact that the assets supporting them were invested for longer terms. The company was unable to sell assets quickly enough to meet these requests and voluntarily sought state insurance department supervision. The cause of these problems was a mismatch between the term of the liabilities (due to the seven day redemption option) and their underlying assets, which, because of a downgrade, led to a liquidity crisis.

3 Further reference material is available from the 2000 Report of the Life Liquidity Work Group of the American Academy of Actuaries to the NAIC’s Life Liquidity Working Group. This report is available at the Academy website at www.actuary.org

• The size of the company may limit access to capital markets. If a company is too small, it may not have the funding choices available to larger companies. On the other hand, if a large company is forced to liquidate billions of dollars of assets at once, the marketplace may not be able to absorb the volume at fair value.

• Immediate demands for cash payments can be a risk if cash is in short supply. An unpredictable cash demand is a larger risk. If a funding agreement has a 7-day put option, the issuer has only one week to collect the cash needed to satisfy the obligation. A predictable cash demand is less of a risk. A well-managed company can structure its assets in such a way so that it has enough cash to cover the known obligations. GIC’s with fully predictable pay-out dates and no surrender provision should have minimal liquidity risk in a well-managed company because the cash flows are predictable and planned for.

• Unpredictable deferred or deferrable demands on cash increase liquidity risk. However, the risk diminishes with longer deferral periods. For example, a cashable GIC contract may have a 90-day delay provision, which under normal circumstances gives the company a reasonable amount of time to access its liquidity sources.

• Insufficient ability to borrow short term through bank lines of credit, commercial paper, etc., increases the liquidity risk.

• Lack of diversity/fungibility in either the liability or the asset portfolio when analyzed by product, region, industry, creditor, etc. can create an over-concentration of illiquid assets, such as real estate or thinly traded securities, thus increasing the liquidity risk.

• Finally, liquidity risk can arise during a crisis in the capital markets. When market price moves become extreme, and their volatility increases dramatically, normal correlations break down. As investors begin to exhibit the same behaviour, assets can become non-tradable or illiquid.

5.49 In the case of a large U.S. life insurer that suffered a significant liquidity event, the event was triggered by a downgrade in its credit rating. The contributing factors to liquidity risk were large funding agreement contracts held by relatively few, sophisticated customers; these funding agreements contained 7-day put options. The ratings downgrade caused large amounts of GIC’s to suddenly become cashable on very short notice.

5.50 The WP believes that liquidity issues in an insurer are typically triggered by difficult-to-predict events, frequently involving policyholder behaviour because of various operational risk events (e.g., ratings downgrade) and recommends that liquidity risk be subject to Pillar II rather than Pillar I assessment.

5.3 Risk Measures

5.51 Internal models produce probabilities of all possible outcomes of each component of the insurance company’s risk that is included in the model. The sum of the outcomes of all risks combined is described as the “aggregate” outcome, usually measured as a “loss.” The aggregate loss is described through a probability distribution, which measures the likelihood of all possible outcomes. A “risk measure” is a function of the probability distribution of losses. It is used to determine either the total capital requirement (based on the aggregate distribution of losses) or an indicated capital requirement for a component (based on the loss distribution of the component risk only).
5.52 The following diagram portrays a Normal (so named due to its distinctive shape) distribution of losses. This type of a distribution may reflect the statistical characteristics of some types of risks or be used as an approximation for other risks. This diagram displays the mean of the distribution as well as three types of risk measures, the standard deviation, Value at Risk (VaR – shown on this diagram at the 95\textsuperscript{th} percentile) and Tail VaR.

5.53 Specifically the definitions of these risk measures are:

- Value-at-Risk (VaR) is a quantile of the distribution. For example, the 95\textsuperscript{th} percentile of the distribution is the value for which there is a probability of exceedence of 5%.
- Standard Deviation of the distribution is a measure of the degree of uncertainty.
- Tail-Value-at-Risk (TVaR) is the quantile VaR plus the average exceedence of that quantile if such exceedence occurs. For example, the 95\% TVaR is the arithmetic average of all VaR’s from the 95\textsuperscript{th} percentile on.

5.54 In the next diagram, a skewed distribution is shown. This distribution features a “fatter tail” than the Normal distribution. Risks subject to infrequent but sizeable losses (perhaps catastrophic losses) have “fat tail” distributions. Many insurance risks have skewed distributions. Note the impact of the skewness on the three risk measures. The advantages of using TVaR as a risk measure for solvency assessment purposes are clearly shown in these diagrams since it is the only one of the three risk measures to indicate the amount of catastrophic losses above a certain confidence level.

Copyright © 2004 International Actuarial Association
As is the practice in many areas of financial risk management, it is often useful to begin with the assumption that losses form multivariate lognormal distributions. In many cases this will be a more appropriate assumption than the multivariate normal assumption in an insurance context.

5.4 Risk Management, Mitigation and Transfer

An insurer can take a number of steps to lessen the risk associated with its business. These include the purchase of reinsurance, securitization of a portion of its asset or liability portfolio, hedging of financial guarantees using derivative instruments, the use of product design to pass risk on to the policyholder, as well as active risk management. To the extent that these measures effectively reduce a company’s risk, they should be given appropriate recognition in the calculation of a company’s required capital. The difficulty lies in properly assessing the actual degree of risk that has been transferred from the insurance company in these arrangements.

5.4.1 Reinsurance

Reinsurance is a common way for insurers to manage their risk. In the case of reinsurance in the normal course of business, or indemnification reinsurance, the insurer retains the risks inherent in the original policies sold, while the reinsurer and insurer separately agree to exchange certain specified payments. This has the impact of transferring a portion of the insurer’s risk for those policies to the reinsurer. Indemnification reinsurance can be structured to permit the policyholder to retain varying degrees of risk (e.g., via deductibles, coinsurance, captive reinsurance, retrospective premium arrangements etc.). The presence of a reinsurance contract exposes the insurer to the risk of counter-party default.

Reinsurance can be used to reduce volatility, uncertainty and extreme event risk. For example, some types of insurance can be structured to directly insure against catastrophic events such as earthquakes or hurricanes. They succeed by limiting or “spreading” the risk due to one event through the use of reinsurance to limit their exposure.
5.59 Reinsurance contracts can contain a variety of financial arrangements that specify which party holds actuarial reserves for the business being reinsured. It is important to recognize that where the liabilities are held may not fully indicate which party has the risk. It is also important to recognize that certain forms of reinsurance, generally labelled as financial or finite reinsurance, are actually structured to provide financing by reinsurers to direct writers with only a minimal transfer of real risk.

5.60 In some jurisdictions, reinsurers are subject to regulation and supervision similar to that applied to direct writing companies. Also some jurisdictions require foreign reinsurers, though not directly regulated by the jurisdiction, to maintain sufficient funds locally to support the business they have assumed within the jurisdiction. In both these circumstances, the WP believes it is appropriate to grant credit within a capital requirement to an insurer that has passed on some of its risks through reinsurance. However, this granting of credit should be conditional upon verification that a real transfer of risk has taken place. In addition, the capital credit must recognize the counterparty risk being assumed by the direct writer.

5.4.2 Hedging

5.61 Hedging transactions result in a net reduction in risk as the insurer assumes an offsetting risk to one it currently holds. The insurer still retains the original risk but the offsetting hedging transaction results in a net reduction in risk for the insurer. It is important to note that the insurer assumes additional counter-party default risk as a result of the hedging transaction unless the hedge is a “natural” hedge. A natural hedge occurs when a company can offset risks in different lines of business. For example, writing both life insurance and life contingent annuities for similar groups of policyholders may help to provide a hedge against the impact of improving mortality.

5.62 Recognition of natural hedges introduced when an insurer writes complementary lines of business, can be introduced at the company-wide level once the various individual risk components of a capital requirement have been calculated.

5.63 Financial hedges involving the use of derivative instruments are used by some insurance companies to offset certain financial guarantees (with respect to interest rates or equity markets) that they have given to their policyholders. Before granting credit for financial hedging in a capital requirement, the supervisor should be comfortable that the company’s hedging program is well formulated, is consistent with financial economic theory and effectively provides the desired hedge. The supervisor might also require assurance that financial markets offer a sufficient supply of the required derivative instruments and that the company’s personnel executing the hedging strategy are competent and knowledgeable concerning financial economics. Financial hedges will usually be used only by more sophisticated companies. Credit for these programs within a capital regime will depend upon the demonstrated effectiveness of the program. This is likely to be possible only when internal models are being used to determine capital requirements for the risk that is being hedged. The WP does not propose to include an adjustment for hedging in the standardized factor-based approach, recognizing that the inability to adjust for hedges (or other market-driven risks) is an important shortcoming of standardized factor-based approaches.

5.4.3 Participating Insurance

5.64 Many insurance policies, particularly life insurance, are sold on a participating or with-profits basis. Under these contracts, the insurance company’s experience with respect to this block of business is shared with policyholders through the payment of a policyholder dividend or a bonus; the dividend can take several forms including a cash payment, a credit towards the next premium or an additional amount of paid-up insurance. The argument is made that if a company’s
experience with respect to participating business is unfavourable, then it can pass that bad experience on to its policyholders through a reduction in the bonus or dividends.

5.65 In addition, some companies offer policies that contain adjustable or non-guaranteed policy elements. These elements may include premiums, interest credited to the policyholder’s account, or charges against the policy for mortality or expenses. Policies often contain limiting values that place constraints upon the company’s ability to freely adjust values. For these policies, adjustments can only be made to future policy values. There are also policies, more in the nature of investment contracts, where the investment earnings credited to a policyholder are directly related to a financial index or the return on a designated portfolio of assets.

5.66 The WP suggests it would be appropriate to grant some credit within a capital requirement for risks that are passed through to, or shared with, policyholders under the various mechanisms described above. However, this credit should only be given when the supervisor is satisfied that the insurance company has in place a policy and practice of reducing the dividend or bonus scale or adjusting policy elements in its favour when it is subject to adverse experience. This satisfaction should be based upon explicit demonstration by the insurer of its policies and practices. Moreover, the supervisor should also be satisfied that the constraints placed upon insurers by the concept of “policyholders’ reasonable expectations” with respect to participating policies, or the limits within adjustable policies, do not interfere with the company’s ability to share unfavourable experience with policyholders consistent with its policies and past practices.

5.67 Since the determination of an unfavourable shift in experience may require a significant amount of time, and since reluctance has been observed on the part of many insurers to reduce bonus or dividend scales very quickly, it is not appropriate to allow complete credit for risk generated through participating or adjustable policies.
6. Standardized Solvency Assessment

6.1 Introduction

This section outlines the key considerations that should be considered in designing and selecting a standardized solvency assessment approach for Pillar I insurer capital requirements. The determination of a specific set of requirements for a given jurisdiction should be developed in accordance with these considerations.

6.2 As stated earlier, the optimal approach to assessing insurer capital requirements would result in a requirement that is determined separately for each insurance company so as to produce a capital value most appropriate for that company. This approach can be complex, involve the extensive development of company-specific risk models and could require a degree of technical sophistication that may be beyond the abilities and resources of some insurers or jurisdictions.

6.3 Consequently, it may frequently be more practical to begin from the other end of the spectrum with a standardized approach. A family of standardized approaches is possible, ranging from the simplest and most objective approaches (e.g., set of risk factors common for a jurisdiction that could be multiplied by a company’s relevant exposure amounts) to more complex formulaic approaches, which permit some use of an individual company’s experience.

6.4 The standardized approach must be designed and calibrated to reflect the circumstances of the jurisdiction. In so doing, the key principles of insurer solvency assessment must be respected to the greatest extent possible. Since this approach is meant to determine a minimum value for capital for all companies licensed to conduct business, the factors would be expected to be fairly conservative. It is important to recognize that while a standardized approach may ease the burden of annual computation on each company, considerable research, analysis and fitting of the standardized approach selected will be required at the outset of the new approach by the jurisdiction itself and on an ongoing basis as new product and market risks evolve over time.

6.2 Range of Standardized Approaches

6.5 The design of a standardized approach begins with recognition that the risks assumed by an insurer have identifiable characteristics. Frequently, risks can be analyzed by their frequency and severity (and even in cases where claim incidence and cost cannot be separately estimated with any confidence, the alternative aggregate loss estimate is a proxy for “frequency x severity”). The combination of frequency and severity results in losses whose distribution (either probability or cumulative loss) is of interest in solvency assessment. In particular, the tail of the distribution is important for solvency purposes.

6.6 The most simple standardized approaches would apply a factor or scale of factors to an exposure amount. These factors would be designed to provide for the tail of the distribution. For example, mortality risk could be provided for by multiplying a factor or scale of factors by the exposed amount at risk. Of necessity, such a simple approach attempts to combine volatility, trend, level and catastrophic risk for all products for all companies into one factor or scale of factors.

6.7 Somewhat more complex standardized approaches identify many more components of insurer risk for separate determination of a capital requirement. Additional complexity can be added to allow for risk concentration and diversification. Once again, such approaches apply industry wide norms that will not reflect an individual company’s specific circumstances. Of necessity, a conservative approach to factor setting will be required. While adding many more risk components to the standardized approach may help to better assess the dimensions of an insurer’s solvency position, the increased complexity may result in spurious levels of perceived accuracy.
6.8 Some of the more complex standardized approaches begin to approach the accuracy of company-
specific internal risk models in assessing risk. For example, some approaches would allow the
insurer to input their expected frequency and/or severity data into a standardized computational
model. Also input to the model would be jurisdiction specific parameters relating to the shape of
the respective frequency and severity distributions. These inputs might be provided by the
supervisor.

6.9 In building a standardized approach, appropriate recognition needs to be taken of risk
dependencies. The simplest approach involves building a correlation matrix between risks. A
conservative approach would allow for full correlation between risks. The company’s aggregate
risks would then be determined by adding together all of the individually determined capital
requirements. In reality, there is frequently some degree of (but less than full) correlation
between risks and the impact of correlation on the company’s aggregate risks can be quite
significant.

6.10 It should be remembered that for some risks, a factor-based approach will not work due to the
uniqueness of the risks covered from company to company, the difficulty in defining a loss
distribution or the importance of infrequent yet catastrophic losses. In these situations, other tools
besides factors (or in addition to factors) will need to be implemented.

6.2.1 Development of a Standardized Factor-Based Approach

6.11 A standardized factor-based approach requires calculating the products of measures of risk
exposures and specified factors. The results are summed with an adjustment to the sum to
recognized dependencies, diversification, hedging, matching and other risk interactions. This
allows for risk reduction methods to be recognized directly. Two approaches are described in the
following paragraphs.

6.12 The first standardized approach for a set of risks can be described through a probability
distribution of the amount of funds required to support the specified future liability associated
with the set of risks. Setting the requirement at a level that provides a high probability of
solvency (say 99%) requires determining the quantile (e.g., the 99th percentile) of the distribution
of the amount of funds required. This quantile can always be described in terms of the mean and
standard deviation of the distribution as $\mu + k\sigma$, where $\mu$ represents the mean or expected loss
outcome and $\sigma$ represents the standard deviation or volatility of loss outcomes. The quantity $k$ is
a factor that varies depending on the quantile chosen and the shape of the distribution of loss
outcomes. For example, if the distribution is Normal (Gaussian), and the solvency standard is
95% then $k$ is 1.64; if it is 99% then $k$ is 2.33. If the distribution is different from Normal, then $k$
is also different. The factor $k$ may be increased to add a greater safety margin if the distribution
has a heavier tail than the Normal or if there is additional uncertainty about the mean and
variance. The factor $k$ will vary by type of insurance company. Heavier tails will require larger
values of $k$. For example, a life reinsurance company with only short term mortality risk
coverages, will likely have a distribution that is not very different from Normal. On the other
hand, a general (property/casualty) insurer may have a distribution that is much heavier in the tail
due to the greater possibility of extremely large losses as a result of the characteristics of the
individual underwriting risks or because of high correlations amongst risks. Thus for
property/casualty insurers, $k$ would be expected to be larger.

6.13 A second approach would be to approximate the distribution of the insurer’s amount of funds
with a specific distribution (e.g., lognormal) and calculate the measure of risk (such as TVaR) at
the desired confidence level (say 99%) to determine the total balance sheet requirement.
6.14 Under the first standardized approach, the mean $\mu$ is considered to represent the best estimate liability while the $k\sigma$ represents the total capital requirement. This reflects the total balance sheet approach recommended in this report. Note that any amount of conservatism that is built implicitly or explicitly into the statutory or GAAP financial statements (when the reserve is higher than $\mu$) should be recognized as “hidden” capital since it partly protects the company against adverse outcomes. Under the second approach, the observed $\mu, \sigma$ and any other parameters can be used to estimate the parameters of the specified distribution from which the risk measure is derived.

6.15 The discussion in the last paragraph can be applied at the level of product, risk type or line-of-business (LOB) level in the company. Under the first approach, if the LOB’s are labelled using subscripts, then the total balance sheet requirement $c_j$ for $\text{LOB}_j$ can be rewritten as $c_j = \mu_j + k_j \sigma_j$. Note that all three elements are specific to $\text{LOB}_j$. The factor $k_j$ can then be made specific to $\text{LOB}_j$.

6.16 The capital requirement for $\text{LOB}_j$ is then $k_j \sigma_j$. If this is normalized by the expected losses, the capital requirement is $c_j = \mu_j k_j v_j$ where $v_j$ is the coefficient of variation (CoV) or the ratio of the standard deviation to the mean. The capital requirement can be written as the product of three terms since:

1. $\mu_j$ representing the expected losses an “exposure” measure unique to the company and must be calculated by the company;
2. $k_j$ is specific to the LOB and not the company, and can be prescribed by the supervisor; and
3. $v_j$ depends on both the LOB and the size of the LOB for the company, and can be designed with the option of having a formula reflecting industry characteristics for the LOB and incorporating the company’s size.

6.17 It should be noted that the exposure measure can be based on simple quantities such as premium volume or be based on more complex probability models reflecting frequency and severity. The capital requirement formula must reflect all future contractual obligations of the company (i.e., not only already incurred or outstanding claims but those that are expected in the future from existing contracts).

6.18 One of the challenges to be faced in developing any standardized approach is that the unintended consequence of its actual operation may be counterproductive to its intended effect. For example, a standardized approach that seeks to multiply gross premiums by a factor, while well intended, also has the effect that an insurer seeking greater financial soundness is actually penalized for increasing the profit margins in its premiums. In a similar fashion, a standardized approach which relies on statutory or GAAP (rather than best estimate) liabilities will inadvertently increase a company’s capital requirement in the event that it selects a more conservative (i.e., not due to underlying experience) reserving basis. Both of these examples represent the difficulties in designing standardized approaches that remain faithful to the core principles for solvency assessment as laid out in this report.
6.19 The capital requirements of the LOB’s need to be combined into a single capital requirement for the whole company. Simply adding them together will fail to recognize possible diversification between them. The formula,

\[
c = \sqrt{\sum_j c_j^2 + \sum_{i \neq j} \rho_{i,j} c_i c_j}\]

allows for diversification of risks, where \( \rho_{i,j} \) represents the “correlation” between LOB\(_i\) and LOB\(_j\). If the correlations are all equal to 1, then the formula is equivalent to summing all the capital requirements for the LOB’s. If the LOB’s are all mutually independent, then full diversification is possible and the correlations are all equal to 0 and the second term under the square root sign becomes zero. In practice the correlations between LOB’s need to be estimated or prescribed. For example, if it is recognized that there is a strong correlation between two risk types (e.g., yields on bonds and yields on mortgages), then the supervisor could prescribe that a specific correlation could be set to 1 in order to have some additional conservatism. Similarly if the correlation between two LOB’s is felt to be negative (e.g., annuity mortality and life insurance mortality), the supervisor could prescribe a correlation of 0 to be used so that additional conservatism be incorporated into the formula. In general, it is recommended that the correlation between all pairs of risk types be estimated.

6.20 This “correlation” need not be the standard linear correlation found in statistics textbooks. In particular, it could be a “tail correlation” to incorporate the possibility of simultaneous adverse outcomes in more than one LOB. It can also reflect the choice of “risk measure” used. If the risk measure places greater emphasis on adverse outcomes, then the correlation will be larger than otherwise. The appendices to this report include more technical material supporting the development of correlation formulas.

6.21 Under the second standardized approach each \( \mu_i \) and \( \sigma_i \) can be used to calculate the mean, \( \mu \), and standard deviation, \( \sigma \), of the amount of funds for the entire insurance company with the following formulas.

\[
\mu = \sum_j \mu_j
\]

\[
\sigma = \sqrt{\sum_j \sigma_j^2 + \sum_{i \neq j} \rho_{i,j} \sigma_i \sigma_j}
\]

\( \mu \) and \( \sigma \) can be used to parameterize a particular (e.g., lognormal) distribution and the final capital requirement will be equal to the selected risk measure (e.g., TVaR(95)) minus the liabilities.

6.3 **Underwriting Risk – Life Insurance**

6.22 In assessing underwriting risk for an insurer, the basic principles for determining a standardized approach apply as laid out in the section above. However in “drilling down” into any layer of detail, there are distinctive characteristics of the various areas of life insurance that may require special consideration. This section describes some of the special considerations involved in developing standardized approaches for underwriting risk within the life insurance business.
6.23 Some of the special considerations of life insurance, which require consideration in the development of any standardized formula, include the following:

- heterogeneity of risk (even within established “classes” of insurance business)
- importance of mortality/morbidity, lapse and expense (underwriting) risks
- substantial effects of correlation between different underwriting risks
- long-term nature of the majority of the business
- significant role played by reinsurance (especially in relation to concentration of risk)
- difficulty in modelling policyholder behaviour for some products
- importance of adjustable product features in some products (e.g., participating or with-profits policies, etc.)

6.24 Any standardized approach for life insurance will need to take account of these characteristics and will require the classification of all life insurance business in each supervisory jurisdiction into defined product types – the level of detail in the definition effectively being in the control of the supervisor in the jurisdiction under consideration.

6.3.1 Mortality Risk

6.25 In this section an overview is provided of some of the standardized approaches that can be used to calculate capital for mortality risk. Several techniques for calculating the capital requirement for the key risk components of mortality for a life company are proposed below and, where possible, practical standardized measures will be recommended for their estimation. The mortality risk components are

- volatility
- catastrophe
- trend uncertainty
- level uncertainty

6.26 For illustrative purposes, the risk measure used is VaR with a degree of protection set at 99.5% for these approximations. As noted earlier in this report, the WP recommends the use of consistent measures of risk such as TVaR. However, in this example, there is only a small difference in the results between the VaR and TVaR measures with appropriately adjusted confidence levels. The degree of protection has been chosen solely for illustrative purposes. The WP recommendations for degree of protection and its relationship with the risk measurement time horizon are discussed earlier in this report.

6.27 In the models below, the expected mortality claim level or risk premium $RP$ is:

$$RP = \mu = \sum_i q_i X_i$$

where $q_i$ and $X_i$ are the mortality rate and amount of insurance for the $i^{th}$ insured person. In general it is assumed that the number of deaths are Poisson distributed. The total claim level is Compound Poisson distributed.
6.28 This means that the standard deviation $\sigma$ and the skewness $\gamma$ of the distribution can be found in the following way:

$$
\sigma = \sqrt{\sum_i q_i X_i^2}
$$

$$
\gamma = \sum_i \frac{q_i X_i^3}{\sigma^3}
$$

Volatility

6.29 Traditional volatility risk is often calculated using a simulation model with many scenarios generated based on parameter input(s) into a Monte Carlo process. A good alternative is an analytical approach, the Normal Power approximation, using the first three moments of the Compound Poisson distribution. This approach will be less (computer) time-consuming than simulation models.

6.30 The capital at a 99.5% confidence level in the Normal Power approach is:

$$
c_{\text{volatility}} = \sigma(2.58 + 0.94\gamma)
$$

In this case, the value of $k$ is $2.58 + 0.94\gamma$ at the 99.5% level of confidence.

6.31 Under typical circumstances this approach can be further simplified. With $#$ as the number of insured risks and the average $q_i$ is around 0.0025 the capital can be calculated as follows:

$$
c_{\text{volatility}} = \left(\frac{77.4}{\sqrt{#}} + \frac{942.7}{#}\right)\mu
$$

Volatility example

6.32 Three portfolios are used to test these methods. The three portfolios have each their own characteristics.

<table>
<thead>
<tr>
<th>Portfolio</th>
<th>Number insured(#)</th>
<th>Max insured/ average</th>
<th>Skewness</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>125,970</td>
<td>11.6</td>
<td>0.13</td>
</tr>
<tr>
<td>2</td>
<td>60,777</td>
<td>40.3</td>
<td>0.77</td>
</tr>
<tr>
<td>3</td>
<td>24,570</td>
<td>14.7</td>
<td>0.38</td>
</tr>
</tbody>
</table>

6.33 The results for the volatility capital are (% Risk Premium):

<table>
<thead>
<tr>
<th>Portfolio</th>
<th>Simulation</th>
<th>Normal Power</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>22.7%</td>
<td>22.8%</td>
</tr>
<tr>
<td>2</td>
<td>69.9%</td>
<td>68.1%</td>
</tr>
<tr>
<td>3</td>
<td>57.2%</td>
<td>57.4%</td>
</tr>
</tbody>
</table>
6.34 Assuming that reinsurance caps the individual sum at risk at 1,000,000 the volatility gives the following results:

<table>
<thead>
<tr>
<th>Portfolio</th>
<th>Simulation</th>
<th>Normal Power</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>22.9%</td>
<td>22.8%</td>
</tr>
<tr>
<td>2</td>
<td>37.9%</td>
<td>37.6%</td>
</tr>
<tr>
<td>3</td>
<td>56.6%</td>
<td>55.8%</td>
</tr>
</tbody>
</table>

6.35 These results indicate that the Normal Power approximation provides results that are highly accurate when compared with results based on simulation. Therefore, this approximation can be used in establishing a capital requirement for this component of mortality risk.

**Catastrophe**

6.36 Beyond “normal” random fluctuations (volatility) in mortality experience from one period of time to the next, extra capital is needed for extreme events that result in high positive deviations in the claim level. These events can be caused by

- severe epidemic (e.g., Spanish Flu in 1918)
- natural catastrophe (e.g., earthquake)
- terrorist attack (e.g., events of 9/11)

6.37 Due to a lack of data it is difficult to model this kind of risk and a very simple approach may be the most useful and appropriate. The capital for catastrophe risk can, for example, be based on portion of the expected number of deaths during one year. Based on the experience of the Spanish Flu epidemic, a doubling of one year’s expected deaths may be appropriate.

**Level Uncertainty**

6.38 Level uncertainty is caused by the volatility observed in the past. This can make it difficult to estimate the “real” or “true” current average mortality. The same kind of model as in the volatility risk can be used to calculate this risk. However, the potential impact on the liability must be determined because level uncertainty involves the misestimation of the mortality assumption for all future years. This makes it difficult to find a simple factor approach.

6.39 One approach would be to “shock” the present value amount of the policy liabilities using best estimate mortality rates. To find this shock the same kind of approach can be used as for volatility (e.g., Normal Power).

**Level Uncertainty Example**

6.40 As an example, let us use Portfolio 1 with an assumption that the best estimate mortality assumption had been derived from three years of experience. Further, the number of insured persons were

- Year (-3) 97,013
- Year (-2) 101,057
- Year (-1) 116,651

For a total number of observations of 314,721. Therefore, based on the factor approach the 99.5% shock on the best estimate mortality rates is:

\[
\left( \frac{-77.4}{\sqrt{314721}} + \frac{942.7}{314721} \right) = 0.14
\]
6.41 Therefore, the capital for level uncertainty can be based on liabilities calculated with 14% higher mortality rates (above best estimate, or BE, assumption) minus liabilities based on BE mortality rates. The impact of this on the liabilities will depend on duration, product and interest rate.

The effect of 10% higher mortality rates on single premium business is given by:

<table>
<thead>
<tr>
<th>Duration/Interest</th>
<th>Endowment</th>
<th>Pure endowment</th>
<th>Term</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>4%</td>
<td>8%</td>
<td>4%</td>
</tr>
<tr>
<td>5</td>
<td>0.07%</td>
<td>0.14%</td>
<td>0.73%</td>
</tr>
<tr>
<td>10</td>
<td>0.19%</td>
<td>0.41%</td>
<td>1.14%</td>
</tr>
<tr>
<td>20</td>
<td>0.44%</td>
<td>1.00%</td>
<td>1.54%</td>
</tr>
</tbody>
</table>

6.42 These results indicate that the impact on a pure endowment is independent of the interest rate. The additional capital required for a 10% mortality change is simply the percentage in the table multiplied by the net single premium. On the other hand, a simple approach for term insurance can be to simply shock the liabilities by 10%.

**Trend Uncertainty**

6.43 Another mortality risk component is trend uncertainty, the difficulty in accurately assessing the future direction (e.g., improvement) of the mortality assumption in future years. With many product terms extending for the lifetime of the insured, this can be a considerable risk, especially for payout annuities. It is difficult to model mortality trend uncertainty in a simple way. The result depends on product, duration and interest rate. The graph below illustrates the value of trend uncertainty for a variety of products. The vertical axis indicates the value of trend uncertainty as a percentage of the underlying liability amount. The horizontal axis displays the remaining duration of the liability.
6.44 A simplified approach to provide for trend uncertainty could be to apply a factor multiplied by the present value amount of the liabilities (see following formula). The factor might be expressed as the lesser of $\alpha$ and $\beta$ times the product duration $n$. Some sample values of $\alpha$ and $\beta$ are also given in the table below.

$$c_{\text{trend}} = \min\{\alpha, \beta n\}(\text{liability})$$

<table>
<thead>
<tr>
<th></th>
<th>$\alpha$</th>
<th>$\beta$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pure endowment</td>
<td>7%</td>
<td>0.35%</td>
</tr>
<tr>
<td>Endowment</td>
<td>3%</td>
<td>0.15%</td>
</tr>
<tr>
<td>Term</td>
<td>30%</td>
<td>1.50%</td>
</tr>
</tbody>
</table>

The uncertainty trend for a whole life annuity can be based on 4% of the liabilities ($x>55$). These calculations of trend uncertainty are based on a 99.5% confidence level.

6.45 The final capital requirement for mortality risks should provide for each of the components described in the preceding paragraphs, volatility, catastrophe, level and trend uncertainty. To the extent that the mortality experience is shared with the policyholders then corresponding credit should be granted in the capital requirements.

6.3.2 Lapse Risk

6.46 The risks posed to an insurer by an unanticipated rate of policy lapses, terminations or surrenders (collectively referred to here as ‘lapse risk’) are varied and complex. The treatment of lapse risk within a capital requirement will also vary from jurisdiction to jurisdiction. This variation is increased by the differences in how provision for lapses is or is not made within policy liabilities or actuarial reserves. It should be noted that in many jurisdictions, the valuation of liabilities is made using a modified net level premium approach that does not explicitly take lapses into account. The methodology used in other jurisdictions, particularly that based upon gross premiums, does make explicit recognition of the effect of lapses. The latter includes the valuation method being proposed in connection with the new international accounting standards being developed by the IASB.

6.47 There are two primary effects of unanticipated lapse rates. The first involves the payment of surrender or termination values. The relationship of the amount of a surrender payment to the value of the liability being held in respect of a particular policy is of great importance. When a policy lapses, the company pays the surrender value and ‘receives’ the actuarial reserve that is released by the policy’s termination. If surrender values are lower than policy reserves, the company is at risk from lapse rates that are lower than expected, particularly if high lapse rates were anticipated in the pricing of a product. The case that surrender values exceed policy reserves results in higher lapse rates being unfavourable to the insurer. In some jurisdictions these risks are mitigated by regulations. A requirement that a company holds policy liabilities at least as large as surrender values provides partial protection against overly high lapse rates while minimum required surrender values reduce the likelihood that insurers will price their products using an assumption of high lapse rates. It is important to recognize that the relationship between the surrender value and the actuarial reserve is not fixed; it will generally vary with the duration of a particular policy.

6.48 The second primary effect of unanticipated lapse rates is that the insurer may not realise the expected recovery from future premiums of initial policy acquisition expenses. These acquisition expenses may be recognized implicitly in financial statements through the use of modified net level premium valuation methods. These implicit methods generally do not include any provision for unfavourable variations in lapse rates. Recovery of acquisition expenses may also be recognized explicitly through a reduction in policy liabilities or through introduction of a receivable asset. In this latter case, the adjustment to financial values is made subject to a form of
recoverability test. Under the second primary effect, the risk to insurers is generated by lapse rates that are greater than expected.

6.49 Unanticipated lapses can have other effects on the financial condition of an insurance company. For example, anti-selective lapse by healthier lives may lead to deterioration in a life insurer’s mortality experience. This risk may be due to poor product design, an operational risk. In general, this risk is not treated for capital purposes as a lapse risk.

6.50 A capital requirement with respect to the first type of lapse risk requires the division of an insurance company’s policies into two classes: 1) those policies for which actuarial liabilities $L$ are greater than surrender values $S$, and 2) those policies for which $S > L$. The capital requirements would then be of the form $j(L-S)$ or $k(S-L)$ respectively, for appropriately chosen factors $j$ and $k$. A capital requirement in respect of the second type of lapse risk could be of the form $mU$ where $m$ is an appropriately chosen factor and $U$ is the present expected value of acquisition expenses recoverable from future premiums.

6.51 In the case that lapses are recognized explicitly in the valuation of actuarial liabilities, another approach to capital requirements in respect of the first type of lapse risk is available. This requires the division of policies into two classes: 1) those for which an increase in lapse rates results in an increase in policy liabilities, and 2) those for which policy liabilities increase when assumed lapses decrease. The capital requirement is of the form of the difference between a special valuation of policy liabilities and the normal valuation. For the special valuation, the lapse assumption is multiplied by a specified factor greater than one for policies in the first class and by a factor less than one for policies in the second class. As an example, in Canada, lapse rates are doubled for policies in the first class and reduced by one-half for those in the second class.

6.52 The last lapse case, which cannot be addressed in a factor-based approach are those products for which lapse risk does not act uniformly over the products life, such as lapses at early durations which may reduce the company’s exposure to later risks for some policies and not for others.

6.3.3 Expense Risk

6.53 Operating expenses of an insurance company represent a considerable portion of an insurer’s annual costs. The other major element of annual costs would include the change in policy liabilities (i.e., reserves or technical provisions) and policy benefits/claims. Solvency assessment of insurers should also consider the risks involved with the expenses of the company. It is important for an insurer to understand its expenses and their component parts for the purposes of proper product pricing, provisioning, solvency assessment, etc.

6.54 Most important in any analysis of insurer expenses is to obtain the split of expenses between acquisition and maintenance and also between fixed and variable. A table similar to the following should be developed.

<table>
<thead>
<tr>
<th>Expenses</th>
<th>Fixed</th>
<th>Variable</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Acquisition</td>
<td>#</td>
<td>#</td>
<td>Total Acquisition</td>
</tr>
<tr>
<td>Maintenance</td>
<td>#</td>
<td>#</td>
<td>Total Maintenance</td>
</tr>
<tr>
<td></td>
<td>Total Fixed</td>
<td>Total Variable</td>
<td>Total Expenses</td>
</tr>
</tbody>
</table>

6.55 Fixed expense are not those ‘fixed per policy expenses’ used in profit testing or embedded value calculations that are invariant to the size of the policy. The ‘fixed expenses’ are those expenses that do not vary in proportion to the volume of the total new and existing business at least over the short-term.
6.56 Especially important for assessing the adequacy of provisions and for solvency assessment is a proper determination of the split of expenses between acquisition and maintenance. This split is based on insurer judgement. If too many expenses are allocated to the acquisition category, then a forward looking view of the company’s on-going maintenance expenses will be understated. This may result in the under-provisioning of such expenses in the liabilities and an overly optimistic view of the company’s future financial condition.

**Acquisition expense risk**

6.57 New business consists of the sales of new policies. Although the value of future sales beyond the current year are not included, acquisition expense risk exists since acquisition expenses are partly fixed and the company may be subject to variances in new business volume.

6.58 Theoretically, a distribution could be fitted to model the past ratio of the actual and the planned sales volumes. The capital requirement could then be determined from the tail of that distribution.

6.59 A simple method that could be used to calculate the economic capital would be to calculate the capital as \( \text{Factor} \times \text{Fixed Acquisition Expenses} \). The fixed acquisition expenses are the fixed acquisition expenses in the subsequent year. The factor can be set at 100% and considers only a one-year time horizon.

**Maintenance expense risk**

6.60 Maintenance expense risk is due to:

- Unexpected changes in the unit cost (assuming the portfolio runs off as expected) and
- Unexpected changes in the volume of the portfolio.

6.61 It would be possible to run multiple projections for the existing business around which a distribution could be constructed in order to estimate the economic capital required for maintenance expense risk. However new business volumes and changes in business strategy have a significant impact on the expense structure of a company. Since in this phase new business beyond the valuation date is excluded we propose a simplified methodology for the calculation of the capital.

6.62 The first component is often related to the misestimation of inflation where this is expected to be a material risk factor. The methodology proposed is that the best estimate inflation assumptions are shocked by a factor (i.e., a 30% increase of inflation in the initial year decreasing linearly to the best-estimate assumption over 5-10 years; or perhaps a 1% increase over the lifetime of the business). The capital would then be calculated as the change in value of expense liability between the best estimate and shock scenario.

6.63 The second component is similar to that for acquisition expense risk and again a distribution could be fitted to model the past ratio of the actual versus the planned maintenance expenses. The basis for the solvency capital would be defined as the 0.5% tail of this distribution.

6.64 However, similar to the acquisition expense capital requirement, a simplified methodology for maintenance expenses may be more practical. A formula such as \( \text{Factor} \times \text{Fixed Maintenance Expenses} \) might be used. The factor would be based on expert judgement and reflect the company specific situation. A factor of the order of 75% might be reasonable and considers a three-year time horizon (i.e., assumes a 25% drop in the business volume and the inability of the company to adjust the fixed maintenance expenses over the period). The 75% factor assumes that the business does not have a material exposure to fluctuations in the equity markets that would impact the expected fee income. In this situation the factor is likely to be lower since equity risk already covers some of the maintenance expense business risk.
6.65 Alternatively, the policy liability including best estimate expense assumptions could be shocked to allow for both types of maintenance expense uncertainty (e.g., inflation and exposure to variable unit costs). The capital would then be calculated as the change in value of expense liability between the best estimate and shock scenario.

**Alternate expense risk solvency calculation**

6.66 The expense risk solvency calculation outlined above separated the risk for acquisition and maintenance expenses and involved determining the fixed and variable expenses. In some situations the classification of expenses into acquisition and maintenance fixed and variable might be impractical or of limited benefit. In particular, this could be the situation in emerging markets where the experience is not stable and assumptions are based on short-term experience.

6.67 An alternate methodology for determining the expense risk capital requirement could involve looking at the expenses of a company in aggregate and simply estimating the economic capital as a Factor * General Operating Expenses. The factor would be based on expert judgement and reflect the company specific situation. General Operating Expenses would be the usual costs incurred in day-to-day operations. This would not include commission costs that are completely variable. A factor of the order of 100% might be appropriate.

6.68 The final capital requirement for expense risks should provide for each of the components described in the preceding paragraphs, acquisition, maintenance inflation and maintenance unit cost. To the extent that the expense experience is shared with the policyholders then corresponding credit should be granted in the capital requirements.

6.4 Underwriting Risk - Non-Life (General) Insurance

6.69 Some key idiosyncrasies of non-life (general) insurance, which require special consideration in the development of any standardized formula, include the following:

- heterogeneity of risk (even within established “classes” of insurance business)
- substantial effects of correlation between different underwriting risks
- difference between outstanding claims liabilities and liabilities because of unexpired risk inherent in unearned premiums
- annual renewal basis for the vast majority of the business
- significant role played by reinsurance (especially in relation to concentration of risk)
- difficulty in estimating separate claim incidence and severity in projecting experience for a minority of the business.

6.70 In summary, any standardized approach for non-life insurance will need to take account of these characteristics and will require the classification of all non-life insurance business in each supervisory jurisdiction into defined lines of business (LOB’s) – the level of detail in the definition effectively being in the control of the supervisor in the jurisdiction under consideration.

6.71 The standardized approach will also require specification for each LOB of a LOB Coefficient of Variation (CoV), a LOB Size Factor (SF), and a LOB Confidence Factor (CF). In addition, a set of Correlation Coefficients (CC) will need to be specified for each pair of LOB’s.

6.72 CoV’s for outstanding claims liabilities would typically be expected to be in the range of 10% to 20% for short tail business and typically in the range 20% to 30% for long tail business. CoV’s for unexpired risk liabilities would generally be expected to be between 25% and 75% higher than the CoV used in the same LOB for the outstanding claims liability.

6.73 LOB Size Factors would be specified to increase the level of capital required for smaller portfolios compared to medium or larger portfolios to reflect the increased impact of non-systematic risk in smaller portfolios.
6.74 For illustrative purposes, a standardized approach applicable to non-life insurance LOB’s might reasonably be used

(a) Correlation coefficients between any pair of classes of business greater than or equal to 25%
(b) Correlation coefficients between any two long-tail classes of business greater than or equal to 50%.

Appropriate coefficients for each jurisdiction would need to be determined.

6.75 A simple illustration of these concepts is set out in the table below which assesses a total capital requirement of a hypothetical insurer to be $9,894 million where total expected losses (before diversification allowances) are $7,425 million.

6.76 A standardized approach of this kind also requires a genuine best estimate of the expected loss in each LOB from both unexpired risks and outstanding claims including incurred but not reported claims. This expected loss needs to be calculated net of reinsurance recoveries expected by the insurer other than for catastrophic losses for which capital requirements are modelled separately. It is recommended that the expected loss for each LOB be calculated either by adopting a frequency- and severity-based calculation based on actual exposures or, if data adequate to support such a calculation is not available, by using a projected loss ratio applied to premium earned. These calculations could be completed using either data supplied by the company or as specified by the supervisor, depending upon the requirements of the supervisor in each jurisdiction. It is important that these expected loss estimates not be made in an unduly conservative fashion so as not to compromise the integrity of the capital calculation methodology as a whole.

</table>
The case study, described in appendix B, is more sophisticated than the simple standardized approach described above. It includes a table of calculated correlation factors that enables the effects of diversification of risk to be included in the model outputs. These factors may be prescribed or may be calculated from underlying data where available. Concentration of risk is identified and appropriate allowance for reinsurance may be included. However, the model does not attempt to accurately measure specific reinsurance effects and it is suggested that existing commercially available risk models be used to assist in this area.

In the model in appendix B, the input of data for each LOB enables the mean and variance of each insurer’s aggregate loss distribution to be calculated. The loss component of the capital requirement, net of catastrophe reinsurance, is then assessed using a lognormal (i.e., skewed) assumption regarding distribution of losses and the TVaR at a “selected” level. The supervisor can select the TVaR level by taking account of the assessed market security requirement and judgement regarding the “goodness of fit” of the lognormal distribution, especially for some of the more heavily skewed risk distributions.

The case study model is simple enough to be represented easily in spreadsheet form and yet detailed enough to allow specific consideration of five of the six key issues listed at the beginning of this section (note that, in respect of the sixth issue, it is a relatively straightforward adjustment to replace the separate claim incidence and mean cost assumptions with an aggregate loss assumption for any selected LOB). The outputs from the model can be designed to be conservative, but enough detail remains in its representation of the business for the supervisor to ensure that any conservatism is not excessive.

The model includes “c” factors that take account of the size of the respective LOB’s and “b” factors that essentially quantify the correlation effects. These b’s and c’s effectively combine to create the “k’s”, as well as allowance for the correlation effect in section 6.2.1.

Neither the standardized approach set out above nor the case study addresses either market risk or credit risk for the general insurer, since these risks are essentially common to all types of insurance.

The model does exhibit some of the necessary flexibility in that inputs may be largely governed by the supervisor or the individual insurer may well be responsible for the large majority of data for the model (and hence making strides towards the creation of an internal modelling approach). It is a member of the range of potential modelling approaches that may be use globally.

In order to extend the “family” of models into use in markets where more sophisticated and accurate data may be available, it is possible to augment the case study model with a number of features to improve flexibility and accuracy. These may include greater “tailoring” of the loss distribution curves to the characteristics of the business (e.g. through the use of a range of formulas or empirical data) and an increase in the range of factors used to model risk correlations). At the other end of the scale, to cater for a market in which actuarial advice is largely absent, it is possible to create a model with a reduced number of entirely prescriptive factors to be applied, for instance, to a broader definition of LOB, or to broad bands of business by size (or by a combination of both) similar to the standardized approach outlined above.

### Underwriting Risk – Disability Income

The following paragraphs provide an illustration of the determination of standardized capital requirements for disability income products.

In the U.S. risk-based capital (RBC) formula for insurance companies, the most significant component for all health insurance products is the underwriting component. The factors for the
asset risk and operational risk are common for all of the insurance products. There is no interest rate risk component for any of the health products. The following description of the process used to determine the formula for the underwriting risk component for disability income (DI) is similar to the process used for the other health products.

6.86 Data and information was collected from all of the DI writers in the U.S. that were willing to contribute to the study. The data collected included incurred claims, earned premiums, policy reserves and tabular claim reserves for as many of the most recent ten years that were available. Interest adjusted loss ratios were calculated using changes in policy reserves that were not caused by a change in basis or reserve formula assumptions. The standard deviation and serial correlation of the loss ratios for each company and for all companies combined were calculated. This process was performed separately for each of the major forms of DI insurance sold in the U.S.

6.87 Other information collected in the study included: number of months after a loss ratio falls outside of an acceptable range until a premium rate change is implemented; the percentage of premium that is eventually changed where a rating action is indicated, expected loss ratio, expense ratio and profit ratio, all expressed as a percentage of earned premium.

6.88 A random walk, stochastic model was then built that, given a specified starting level of capital, calculated the operating gains and accumulated surplus for a five year measurement period. The model assumed a stationary population of in force business, where new sales equal terminations each year. The actual loss ratios collected in the survey were adjusted to reflect the difference between the actual loss ratio and its expected value given the premium rate changes generated by the model resulting from management actions. The time needed to implement a rating action is the “phase in factor” and is developed from the survey along with the upper and lower loss ratio limits that would cause a rating action to be initiated. The model adjusts the randomly generated loss ratio to reflect the indicated premium rate changes each year.

6.89 The model generates a loss ratio, or claim cost per $1 of premium, each year of the projection period which is the sum of three terms:

1. **The previous year’s loss ratio.** The model was run for a three year “seasoning period” prior to the beginning of the actual projection period, so there is a previous year’s loss ratio even for the first year of the projection period.

2. **A correlation deviate for the projection year.** This is based on a random normal distribution deviate with a standard deviation of the loss ratios collected with the adjustment discussed above and another adjustment to reflect the serial correlation calculated from the data.

3. **A term to adjust the current year’s loss ratio** to reflect changes in the premiums that would occur according to the rules for timing and amount of premium actions that would be initiated when loss ratios fall outside of specified limits.

6.90 50,000 scenarios were run for several test initial surplus amounts, calculating the resulting gain or loss and accumulated surplus amount per $1 of earned premium. The gain or loss is the sum of the $1 premium plus expected interest on reserves and accumulated surplus less the randomly generated claim cost, expected expenses and taxes. Ruin occurs when the resulting accumulated surplus falls below zero in any year of the projection period. By interpolation and successive iterations of the process the beginning surplus is found that results in a 5% probability of ruin. This is the RBC amount when expressed totally as a percent of premium.
6.91 A similar stochastic study determined that, if around 5% of claim reserves were added as starting surplus to the amount of claim reserves, the total fund would be adequate with a 95% confidence level. The final formula for the underwriting component adopted the 5% of claim reserves plus a percent of earned premiums, where the percent was reduced to reflect the amount shifted to the claim reserve.

6.92 The analysis was performed on both large and small blocks of business separately, resulting in larger earned premium factors for the small blocks. This was reflected by using a tiered formula, with a larger factor for the first $X$ of premium and a smaller factor for the excess over $X$. As an example, the formula for individual non-cancellable disability income insurance is: 5% of tabular claim reserves plus 35% of the first $50$ million of earned premium plus 15% of the earned premium in excess of $50$ million. Several other types of DI insurance are specified, each having its own unique set of factors. Every U. S. insurance company that writes DI insurance must use this formula and set of factors to determine the underwriting component for DI in their RBC.

6.6 Credit Risk

6.93 Appendix E describes the sources of credit risk for an insurance entity. In summary, they are

- Direct Default Risk: risk that a firm will not receive the cash flows or assets to which it is entitled because a party with which the firm has a bilateral contract defaults on one or more obligations
- Downgrade or Migration Risk: risk that changes in the possibility of a future default by an obligor will adversely affect the present value of the contract with the obligor today
- Indirect Credit or Spread Risk: risk due to market perception of increased risk (i.e., perhaps due to business cycle or perceived credit worthiness in relation to other market participants)
- Settlement Risk: risk arising from the lag between the value and settlement dates of securities transactions
- Sovereign Risk: risk of exposure to losses due to the decreasing value of foreign assets or increase the value of obligations denominated in foreign currencies
- Concentration Risk: risk of increased exposure to losses due to concentration of investments in a geographical area or other economic sector
- Counterparty Risk: risk of changes in values of reinsurance, contingent assets and liabilities (i.e., such as swaps that are not otherwise reflected in the balance sheet).

6.94 From a supervisor’s perspective, the main areas of focus in respect of credit risk are

- inordinate “peaks” of risk due to any number of factors
- reliability and consistency of any external or internal credit rating approaches.

6.95 Given that it is not possible to devise a simple capital framework to incorporate all credit risk factors into account in an accurate fashion, the suggested approach is one aimed at the major factors.

6.96 The approach is clarified by the separation of credit risk into “Type A” (or risk relating to actual assets held and the insurer’s ability to manage its credit loss position) and “Type B” (or credit risk involved with future reinvested assets).

6.97 The time horizon is an important consideration for credit risk. The WP believes that one year is an appropriate limit for capital considerations. The capital requirements should be determined using a degree of confidence consistent with that chosen for other risks.
The Working Party (WP) recommends that the work of the BIS with respect to credit risk capital requirements for banks be also considered for use by insurers in capturing Type A credit risk. In considering the BIS approach, insurance supervisors will need to consider the appropriateness of the time horizon and confidence level assumptions implicit in the BIS approach. Also to be considered is the appropriate treatment of policyholder pass-through features.

By definition the development of standardized approaches for capturing Type B risks is fraught with difficulty. Where these risks are material in an insurer, the supervisor should encourage or even require the insurer to perform appropriate advanced approaches to modelling their Type B credit risk.

Standardized approaches to assessing Type B credit risk might include (from the simplest to the more sophisticated):

a. Where it is not possible to directly compute the present value of future liability cash flows, provision for Type B credit risk can be made approximately by applying a factor to the policy liabilities of long-term business. These factors would need to be tailored to the circumstances of an individual supervisor and their financial reporting structure for these liabilities.

b. Where it is possible to estimate the duration of long term business, provision for Type B risk can be made approximately by applying a credit risk spread to the duration (beyond that of the current assets) and the policy liabilities for long-term business.

c. Where it is possible to directly compute the present value of future liability cash flows, provision for Type B credit risk can be made directly through use of a credit risk spread.

Market Risk

The principal sources of market risk for insurers are

- Interest Rate Risk- risk of exposure to losses resulting from fluctuations in interest rates
- Equity and Property Risk- risk of exposure to losses resulting from fluctuation of market values of equities and other assets
- Currency Risk- risk that relative changes in currency values decrease values of foreign assets or increase the value of obligations denominated in foreign currencies
- Basis Risk- risk that yields on instruments of varying credit quality, liquidity, and maturity do not move together, thus exposing the company to market value variation independent of liability values
- Reinvestment Risk- risk that the returns on funds to be reinvested will fall below anticipated levels
- Concentration Risk- risk of increased exposure to losses due to concentration of investments in a geographical area or other economic sector
- Asset/Liability Mismatch Risk- to the extent that the timing or amount of the cash flows from the assets supporting the liabilities and the liability cash flows are different (or can draft apart) the insurer is subject to asset/liability mismatch risk.
- Off-Balance Sheet Risk- risk of changes in values of contingent assets and liabilities such as swaps that are not otherwise reflected in the balance sheet.

An in-depth discussion of insurer market risk appears in Appendix D.
6.103 Market risk can only be measured appropriately if the market value of assets and liabilities are measured adequately. Market values of assets can generally be deduced from listings in the various securities markets. Because of the lack of a real market for insurance liabilities, the market value of insurance liabilities can be approximated through evolving market/fair value techniques. The concept of the “replicating (asset) portfolio,” may be a useful concept in measuring the market value of insurance liabilities.

6.104 In general, life and health insurers purchase assets to match their liabilities. Historically this has not been true for non-life insurers, who tend to manage separately the results from underwriting and investments. While all of the assets of an insurer are available to provide against adversity, it is common risk management practice for insurers to, implicitly or explicitly, allocate their assets for one of the following purposes:

- support insurance contract liabilities
- provide economic capital
- provide free surplus.

6.105 Sizeable portions of an insurer’s liabilities can have durations (e.g., terms) comparable to readily available high quality liquid assets in the local market. In these situations it is possible to select assets whose cash flows can provide a very close match to the liability cash flows. In other words, a replicating portfolio of assets is available in the market. In this situation, market risk focuses on the volatility of the market value of the actual assets held and the market value of the replicating portfolio of assets and the ability of the insurer to manage that volatility. This type of market risk will be called Type A risk and it also includes the effect of volatility on the insurer’s regulatory capital requirement for these risks and the assets representing that capital.

6.106 The long-term duration of some insurance (especially life insurance) liabilities requires the consideration of long-term rates of reinvestment since replicating portfolio assets of sufficient duration may not be currently offered in the market. Measuring market risk for these liabilities entails considerable uncertainty about the composition of the replicating portfolio and the manner of its reinvestment to mature the underlying cash flows. Lowered rates of reinvestment in the future are typically of concern. In addition, life insurance contracts may contain various complex, long-term options and/or guarantees for which replicating market positions may not currently exist (e.g., death and maturity guarantees on variable annuity products). These latter two types of market risk will be called Type B risk. Type B risk also includes the effect of volatility on the insurer’s regulatory capital requirement for these risks and the assets representing that capital.

6.107 The assets and liabilities of an insurer are subject to Type A and possibly Type B risk. Shorter term insurance contracts without complex embedded options or guarantees are subject to Type A risk. Long-term insurance contracts and/or those containing complex embedded options or guarantees may be subject to both Type A and Type B market risk.

6.7.1 Standardized Approaches for Type A Risk

6.108 The essential ingredients required to assess Type A market risk are

- projected future asset and liability cash flows
- nature of embedded options
- time horizon
- confidence level
- current economic scenario
- series of possible future economic scenarios.
Approximations can be made with respect to these ingredients to simplify the Type A risk determination. The result is a range of standardized approaches from the most elemental to approaches that closely compare to the advanced approach.

One such approximation might use option adjusted durations to represent the price sensitivity of cash flows, the current market value of future cash flows and a set of investment return shocks. The shocks would need to be designed to reflect the time horizon and confidence level desired as well as the possible pattern of adverse scenarios. In this regard, it may be desirable to recognize the more active investment management conducted on closely managed blocks of business (i.e., when the active management holding period is less than the standard one-year time horizon).

Another approximation might require the grouping of future cash flows into various term “buckets” (BIS uses the term “maturity method”). The sum of the cash flows in these “buckets” would be multiplied by factors to produce the capital requirement. These factors would, in theory represent a combination of the above basic ingredients (i.e., time value of money from current economic scenario, adverse shock for desired confidence level and time horizon, etc.). This type of approach is currently used by the BIS in their standardized approach for banks.

A very simple approximation, which depends heavily on broad decisions about the industry’s generalized exposure to Type A risk, is to simply multiply the balance sheet value of insurer assets and liabilities by a table of factors reflecting the presumed presence and size of Type A risk.

The relative merits of each type of approximation need to be viewed by the supervisor in light of local conditions, expertise and inherent industry risk. Objectivity and ease of calculation need to be balanced with greater accuracy, complexity and the overall impact of the method chosen on the management of market risk by insurers and the types of products that are offered in the market place.

To develop standardized approaches for market risks (or other risks for that matter) requires judgement and supervisory tradeoffs depending on the supervisor’s choice of approximation and its method of application. Ideally, the conservatism inherent in a standardized approach should incent insurers to use (to the extent they are able) more advanced methods in the future.

One possible concern in designing more advanced approaches that allow judgement to be used by the insurer (e.g., if the degree of market risk is subject to the asset allocation practices of the insurer) is that the results will be less transparent since there may be opportunities for the insurer to self-select (to some extent) the resulting solvency requirement. It is important for the supervisor to consider in advance the possibilities and significance of such self-selection and to weigh this risk against the risk of accepting a factor approach which (through the use of broad or industry factors) may not recognize fully the risks of a specific insurer. For example, the concern surrounding asset allocation “games” can be addressed directly through a requirement that asset allocation for purposes of the capital requirement must coincide with the insurer’s management of their business.

Particularly in life insurance, some market risk from the total asset portfolio may be transferred to policyholders. This is generally the case in Universal Life business and many forms of adjustable and “with profits” business. Clearly, such assets and the corresponding liabilities should be closely matched (ignoring the non-financial diversifiable risks that may affect these liabilities) and the degree of such sharing of market risk needs to be reflected in the chosen standardized approach.

The following subsections outline some important aspects in selecting a standardized approach for certain sources of market risk as well a possible treatment of dependencies.
6.7.2 Standardized Approaches for Type B Risk

6.118 By definition, the development of standardized approaches for capturing Type B risks is fraught with difficulty. Where these risks are material in an insurer, the supervisor should encourage or even require the insurer to perform appropriate advanced approaches to modelling their Type B market risk.

6.119 Standardized approaches to assessing Type B market risk might include

- For long-term interest guarantees in life insurance and annuity products, determining the present value of future liability cash flows on the presumption that long-term reinvestment returns revert to a conservative view of historical long-term averages.
- For complex options, deriving appropriately conservative factors based on rigorous stochastic modelling of industry-wide data to adequately capture the tail of the loss distribution for the confidence level required.

6.8 Operational Risk

6.120 For the reasons described earlier in this report, the WP believes it appropriate that an insurer’s overall requirement contain a component for operational risk. However, the current shortage experience data in this area will require the determination of an appropriate level for this component of the overall capital requirement will be subject to judgement by the supervisor.

6.121 The approach adopted within Basel II by the banks may be worthy of consideration for insurers. The Basel II approach provides for a “standard”, “basic indicator” and “advanced measurement approach” (AMA). The first two approaches are based on simple multiples of gross income. These simpler approaches are not risk-sensitive. Only the AMA allows the banks credit for various risk management techniques.

6.122 The WP suggests that a reasonable level at which to introduce an operational risk capital requirement may be in the range of 10-20% of the otherwise determined capital requirements. This amount may be actually calculated under a “standard” approach by applying a single percentage (or table of percentages) to one (or a combination) of readily determinable items such as:

- underwriting risk capital requirement
- credit risk capital requirement
- market risk capital requirement
- net earnings
- assets under management

6.123 Alternatively, under a “basic indicator approach” a set of adjustment factors or α’s could be applied to allow the “standard” approach to be modified by major line of business.

6.9 Final Steps

6.124 The WP development of the standardized method has offered alternative approaches for developing factors based on risk exposures within each of the four major risk categories described above. These alternative approaches allow supervisors to choose the desired balance of simplicity and realism within each major risk category that is most appropriate for the given supervisory regime.

6.125 There are also alternative approaches to adjust for risk interdependencies (where not all of the risks can go bad all at the same time). These alternatives allow the supervisor to define the desired balance of simple measures and realistic capturing of aggregate company risk. The
general approach was described previously in paragraphs 6.19 & 6.20 and is also described in section 9.3. Appendix I discusses the theory and value of copulas, which allow a supervisory framework to go beyond simple summing of risks and even beyond efforts to use the square root of the sum of squared risks.

6.126 It must also be remembered that standardized methods, by their nature, may not capture all types of risk accurately or at all. However, within the overall multi-pillar supervisory process all types of risk must be addressed. If risks are not adequately captured within Pillar I (e.g., perhaps liquidity, strategic, legal, etc. risks) then they need to be addressed within either, or both, of Pillar II and Pillar III.
7. Advanced Solvency Assessment

7.1 Introduction
7.1 The standardized approaches for determining capital requirements described in the previous section are intended to be applied uniformly by all companies of a fixed type, life, general or health, in a jurisdiction. Since they are meant to determine adequate capital for a wide variety of insurers, these methods are generally conservative. A jurisdiction may have large and technically sophisticated insurers for which these methods overstate required capital.

7.2 A jurisdiction may wish to allow certain companies to calculate required capital using methods that more directly reflect each company’s particular exposure to risk. This chapter is devoted to a description of possible company-specific methods and to a discussion of issues a supervisor must deal with when allowing a company to apply these methods.

7.2 On Adopting Company-Specific Approaches
7.3 The notion of company specific approaches is found in several places in the Basel Accord. The earliest occurrence is contained in the section on the provision for market risk in a bank’s trading book of assets. Here, banks may be allowed to use their own internal models, subject to specific requirements and conditions being satisfied. These requirements and conditions are discussed at length below. The proposed revision to the Accord, commonly referred to as Basel II, contains several additional examples of company specific approaches, generally labelled as advanced approaches, applied to credit and operational risks. The Working Party’s suggestions represent an extension to insurance of the approach taken in the Basel Accord with respect to banks.

7.2.1 Similarities to and Differences from Basel II
7.4 However, there is a significant difference between banking and insurance. In the Accord, the standardized approach involves measures of a bank’s exposure to risk that are based upon standard accounting conventions that do not involve any element of discretion or choice by the particular bank. This cannot be the case in insurance since many of the most common measures of exposure to risk for an insurer are related to (actuarial) policy liabilities. Actuarial liabilities, whether they are policy reserves for future claims or claim reserves for claims that have occurred but whose amount and time of payment are not known, involve estimates of uncertain future financial values. Although some of these liability amounts may be based upon standard assumptions that are set by law or regulation, the majority of calculations are based upon best estimates selected by a company’s actuaries. The exercise of choice by a company in determining its liabilities is fundamental for insurance in a way that is not found in banking. The standardized approach suggested by the WP makes use of policy liabilities. It follows that the distinction between standardized and company-specific approaches is not the same in this report as it is in the Basel Accord.

7.5 The phrase company-specific approach means a method of determining an insurance company’s capital requirement with respect to a particular source of risk that measures the intensity of the risk in relation to the company’s own experience or the structure of its portfolio of business. By contrast, a standardized approach is one that is based upon standardized factors that measure the intensity of risk, applied to measures of the company’s exposure to risk, or is based upon differing measures of the company’s exposure to that risk (e.g. the difference between policy liabilities based upon the company’s standard assumptions and those based upon specified variations in these assumptions).
7.2.2 Conditions for Approval

When a company calculates the component of required capital with respect to a specific source of risk by means of a company specific approach, it is to be expected that the result will be less than the value for that component that would result from a (more conservative) standardized approach. It is therefore necessary to consider the conditions under which the supervisor could be comfortable with this result. There are two sets of conditions: the first set involves the appropriateness and accuracy of the particular approach taken by the company while the second involves the actions of the company to manage and mitigate the particular risk.

7.7 The supervisor must have assurance that an insurer’s company specific approach is appropriate and gives an accurate measure of required capital. This requires a detailed analysis of both the company’s methodology and of the specific company data used in the calculation. The particular methodology used by a company will vary. It is particularly important that the supervisor examine it and have confidence that it is theoretically correct and properly implemented. In order to adequately evaluate the insurer’s methodology, the supervisor must either have its own technical expertise or have access to independent outside experts. The supervisor must be satisfied with the integrity of the company’s data that will be used in the calculation. Of major concern will be the data’s sufficiency and credibility and the statistical methods used to organize and analyse the data. The qualifications of the insurer’s personnel associated with this approach will also be of concern.

7.8 Required capital can be thought of as a second line of defence protecting an insurance company’s solvency and its policyholders. The first line of defence is solid risk management. If trouble develops that cannot be prevented through management of a risk, then risk based capital should be available to cover the financial losses that emerge. It follows that in order for a supervisor to be content with a lower amount of required capital under a company specific approach, there must be some assurance that the particular source of risk is under control, its effects are well mitigated and there is a reduced need for the required capital. Therefore, in approving a company’s use of an advanced or company specific approach, the supervisor should confirm that the company has in place appropriate risk management processes together with a satisfactory reporting structure.

7.3 Examples of Company Specific Approaches

There are a wide variety of company specific adjustments that could be introduced into a determination of an insurer’s required capital. This report cannot possibly present more than a few of them. Our purpose here is to illustrate some company specific approaches that could be introduced and to point out some of the safeguards and conditions that a supervisor could require or impose before allowing an insurance company to adopt a company specific approach. A supervisor who has understood the approach and the reasoning outlined here should be in a position to adapt these examples to the specific products, insurance markets and legal systems in the particular jurisdiction.

7.3.1 Credit Risk in Basel II

Under Basel II, a bank’s capital requirement for credit risk depends, in insurance terminology, on the frequency of asset defaults and upon the severity distribution of amount of loss give that default has occurred. The Basel II proposal offers two company specific approaches. In the first, a bank may make use of frequencies of default based upon its own asset quality ratings and frequencies of default while using standardized severity distributions. In the more advanced approach, the bank may also use its own severity distributions.
7.11 A bank would have to have experienced considerably more asset defaults in order to derive credible severity distributions than are required to derive credible frequencies. It is therefore to be expected that the more advanced approach would only be available to the largest and most technically sophisticated banks that have experienced extensive defaults, are able to thoroughly analyse their credit experience and have very sound risk management systems in place.

7.12 Banks originate many of their assets through their lending activities. These assets can usually only be assigned a quality or credit rating through use of a bank’s own rating system. The determination of required capital for the credit risk makes use of credit ratings; the use of a bank’s own rating system is regarded as an advanced approach under Basel II. While some insurers do invest in private placements, the bulk of their investments are in publicly traded assets that usually have been rated by a recognized rating agency. It follows that advanced approaches with respect to credit risk are generally more important for banks than for insurers. However, insurance supervisors should nonetheless pay attention to the ratings and attendant assumptions regarding the frequency and cost of asset defaults that are used by insurers.

7.3.2 Risk Pass-Through Products

7.13 A number of insurance products contain features under which the insurance company’s experience (perhaps as measured by its financial results) under these policies is shared in whole or in part with policyholders. If this sharing mechanism is effective in reducing the risk to the insurer, it would be appropriate to recognize this in the calculation of required capital. The sharing mechanism is bound to depend upon the specific product design and the methods that the company employs to administer the business and operate a risk-sharing mechanism. Therefore, recognition given in the calculation of required capital to the reduction of risk to the company will be a company specific matter.

7.14 The type of products that are illustrated here are primarily those of life insurance companies; in particular, we consider participating or with-profits business, as well as certain types of Universal Life and other “new money” or adjustable products.

7.15 The supervisor’s primary concern in allowing an insurer to reflect its risk sharing mechanisms in the determination of capital requirements is to ensure that the insurer will actually be able and willing to reflect unfavourable experience in policyholder dividends or bonus scales. The supervisor will want to examine, among other things, the insurer’s dividend or bonus policy, its history in administering that policy in the past, the effects of any smoothing mechanism that may be in place, as well as the insurer’s competitive position and the perceived effect on the part of company management and the supervisor that a reduction in dividends or bonus due to unfavourable experience would have on that position. The supervisor should take into consideration whether the concept of policyholders’ reasonable expectations would inhibit or restrict the company’s ability to pass on unfavourable experience to its policyholders.

7.16 Consider, the case of asset default risk for participating or with-profits business. An insurer might assert that the costs of asset defaults are passed on to or shared with policyholders and might then request a reduced capital requirement in respect of this risk. The supervisor would want to know that the assets supporting this line of business are clearly segmented from assets supporting other lines so that the assets to which a reduced requirement might apply and from which defaults might be generated are clearly identifiable. The supervisor would next examine the particular risk sharing mechanism (e.g. dividend scale, bonus scale, smoothing account, experience rating) used by the insurer in this instance. The degree of sharing of experience and the speed with which the mechanism effects that sharing would be reflected in the amount of capital relief that is granted.
7.17 In another product design, the investment income credited to a customer’s account may be related to values of a recognized stock market index. The supervisor would want to examine the direct relationship between changes in the index and the amount of earnings (positive and negative) that are attributed to policyholders’ accounts. Capital relief could be close to total when the correlation between changes in the index and interest credited to policyholders’ accounts is close to one and less as this correlation decreases away from one. In order to gain approval for a reduced capital requirement, the company would have to demonstrate this correlation for historical data over, for example, the previous year.

7.18 It is important to distinguish between risk sharing mechanisms that are retrospective and those that operate only prospectively. The mechanisms described above are all retrospective in nature. They enable a company to share past experience with policyholders. Prospective mechanisms allow companies to adjust future premiums in anticipation of expected unfavourable experience. However, they do not provide any relief to a company that has already experienced significant losses. While they do not appreciably eliminate the need for capital, prospective risk-sharing mechanisms do put the company in a better position than it would have if these mechanisms were not in place. It should be noted that in the standardized approach, a capital requirement may be linked to the period for which future premium rates are guaranteed, with longer term guarantees requiring increased capital. Prospective risk-sharing mechanisms are in the nature of adjustments to future premiums and should be reflected in capital requirements as reductions in the length of premium rate guarantee periods.

7.3.3 Experience Rating

7.19 Retrospective experience rating is a feature of many large group insurance contracts. If an insurer has a binding undertaking from the policyholder to fully share in the insurer’s experience with respect to the case, it could be appropriate to recognize this in the calculation of required capital. This would vary by the particular group insurance policy. A reduction in capital could only be granted if the contract wording legally binds the policyholder to pay for case deficits arising from unfavourable experience. Even then, an appropriate provision for counterparty risk will need to be made.

7.20 There are instances where insurers hold policyholders’ funds on deposit with the understanding that the insurer can call upon these funds to make up for a case specific experience rating deficit. If the contact wording was sufficiently binding on the policyholder, it could be appropriate to recognize these deposits as offsets to or reductions in required capital. However, this recognition could only be granted on a policy-by-policy basis since deposits attributable to one policy could not be used to offset unfavourable experience arising from another policy.

7.4 Internal Models

7.4.1 Introduction to Internal Models

7.21 The company specific approaches discussed above involve modifications to or adjustments of a standardized approach. They recognize the availability of company specific information or the nature and effect on company operations and risk of specific product designs or administrative methods. In this section, we consider methods for determining required capital that are not necessarily modifications of the standardized approach. They are, instead, alternate approaches and methods that recognize directly a company’s specific circumstances.
7.22 These approaches are based upon computer models of a specific line of business or segment of a company’s activity. They are usually stochastic in nature and directed to determining the amount of capital that will be sufficient to guarantee the success of that portion of the company’s business to a high degree of probability. These models depend upon scenario generators that can produce a wide variety of scenarios that can affect the future course of the company’s business.

7.23 In general, each company would construct its own model. The model reflects the company’s specific product designs, its various administrative policies and procedures, and other practices including investment policy and claims settlement. It is the role of the supervisor to determine the level of probability that is to be tested as well as the length of the future period over which future model projections are carried out.

7.24 The supervisor must validate and approve the model. This approval extends to the scenario generator. In many cases, the primary stochastic element will be the performance of some set of economic indices such as interest rates or equity market averages over time. Here, the supervisor must be satisfied that the generator is consistent with the theory of financial economics and appropriate for use in the particular application. It is not to be expected that this type of scenario generator would vary significantly from one company to another in the same jurisdiction and operating in the same economic environment. In other models, particularly in the case of general (non-life) insurance, the scenario generator may be used to generate claims experience. In this case, the generator could well be specific to the company and the types of business it conducts. The supervisor would have to be satisfied that the generator captures the range of possible claims that the company could experience.

7.4.2 Uses of Internal Models

7.25 Internal models are currently in use under several capital regimes. These include:

- The Basel I capital requirement for banks allows for the use of internal models in setting the capital requirement in respect of market risk with respect to the block of assets held for trading. This is described in the paper:

- The Canadian capital requirement in respect of life insurance companies, MCCSR, allows the use of internal models for determination of the component of required capital for guarantees with respect to investment products known as segregated funds. The MCCSR is described in the paper:

- Conditions for use of a model are given in:

- The Australian capital requirement in respect of general (non-life) insurance companies permits the use of internal models. This is described in the paper:
7.4.3 Validation Criteria

7.26 The three instances described in the preceding section where internal models have been adopted for required capital calculations embody a similar approach. In particular, they contain similar criteria that supervisors impose before a company’s model is approved for use. The essential criteria are described in the following paragraphs.

7.27 To be valid for use in the supervision of insurance, an internal model needs to be demonstrably capable of meeting a number of criteria in respect of prudence, comparability and consistency within the supervisor’s jurisdiction.

7.28 *Prudential Requirements:* The insurer must demonstrate that the internal model operates within a risk management environment that is conceptually sound and supported by adequate resources. It also needs to be supported by appropriate audit and compliance procedures. A number of qualitative criteria follow from these minimum requirements:

- The insurer should have an independent internal risk management unit, responsible for the design and implementation of the risk-based capital model.
- The insurer’s Board and senior management should be actively involved in the risk control process, which should be demonstrated as a key aspect of business management.
- The model should be closely integrated with the day-to-day management processes of the insurer.
- An independent review of the model should be carried out on a regular basis. (Amongst other considerations, it should be recognised that evolution of the modelling capabilities is to be encouraged)
- Operational risks should be considered

7.29 *Comparability and Consistency Requirements:* The model’s output needs to fit closely with the supervisor’s view of key minimum performance criteria, such as probability of default and other important measures of financial soundness. Quantitative criteria relating to these needs could include:

- A requirement for the model to calculate the capital needed to keep the annual probability of default below a certain level (or levels)
- An ability for calculating the likely spread of economic costs relating to a range of potential outcomes for the business, etc.

7.30 In addition the model should include the capability for specification of the key risk factors for the insurance business. These would include factors relating to both assets and liabilities including:

- Measurement of cash flows for both assets and liabilities
- The risk of changes in outstanding claims valuation due to changes in economic, environmental or experience-related factors
- The risk of changes to the adequacy of premium rates due to changes in economic, competitive or environmental factors
- Catastrophe concentration risk
- Expense risk; and
- The reinsurance security risk and risk of reinsurance cost variability

7.31 The model should include a facility to enable comparability of correlation effects between risk classes as well as a system of stress testing and other scenario-based examinations.

7.32 The model should be in a format to allow a reasonably straightforward detailed review by appropriately skilled representatives of the supervisor to enable a relatively “painless” approval procedure. Note that the preceding validation criteria should be viewed as minimum requirements and different jurisdictions may require stronger conditions for the validation of models.
7.4.4 Internal Models and the Valuation of Liabilities

7.33 The WP has indicated elsewhere in this report a preference for a Total Balance Sheet approach to the setting of capital requirements. This approach is particularly appropriate in situations where the present value of the insurer’s future cash flows can be treated as a random variable whose distribution is derived using an internal model. In this case, policy liabilities can be determined at one point in the distribution and the sum of liabilities and required capital at another. Utilization of the same model, and indeed the same set of calculations, for the determination of policy liabilities also serves to satisfy the requirement expressed in the preceding section that an internal model should be closely integrated with the day-to-day management processes of the insurer and not be used solely for the calculation of required capital.

7.4.5 Internal Models and the Standardized Approach

7.34 There may exist situations in which a stochastic approach is the most natural approach to take in valuing a particular type of liability and determining the associated capital requirement. However, the insurance industry within a jurisdiction may not be at a state of technological readiness that would permit the introduction of internal models by all insurance companies. A possible solution would be to apply a generic model to data collected across the industry. The results of these calculations could be used to determine standardized factors that could be applied to various companies’ measures of exposure to the particular risk. Since these factors would apply uniformly across the industry, they would be chosen with a conservative bias. In this way, an internal model could be used to develop a standardized approach for the particular risk. For the larger and more technically sophisticated insurance companies, the conservative bias of the factors would provide incentive to seek early approval for the use of their own internal models.
8. **Reinsurance**

8.1 One of the most important risk management tools available to all types of insurers is reinsurance.

8.2 Reinsurance refers to insurance purchased by an insurer to provide protection against some or all of certain risks of the insurance policies issued by the insurer. In exchange for the assumption of these risks, the reinsurer receives payment in the form of reinsurance premiums or allowances from the direct writer of the business, the insurer. The insurer cedes either proportional amounts through quota share and surplus contracts, or losses exceeding a predefined threshold through non-proportional arrangements such as excess of loss or stop loss contracts.

8.1 **Reasons for Purchasing Reinsurance**

8.3 Reinsurance is purchased for different reasons. One can generally distinguish between two main objectives: one is the genuine transfer of risk with the goal of risk mitigation, the other one can be described as a risk transfer for the purposes of managing/spreading risk over time or achieving strategic business objectives.

8.4 Genuine risk transfer reasons primarily include

- Limiting large or catastrophic claims. Such coverage generally provides for the reinsurer to pay claims in excess of a certain limit, subject to a minimum number of claims and subject to a maximum amount of reinsurance per event. This coverage provides protection against concentrated claims arising from a single event (e.g., catastrophic events such as storms, earthquakes, or large loss events like plane crashes, loss of property, etc.).

- Limiting Total Claims. Some insurers, especially smaller ones, have need of stop-loss reinsurance to limit the aggregate amount of claims in a given year.

8.5 Strategic or financial objectives include

- Increasing new business capacity. One of the most common reasons for the purchase of reinsurance is to enable an insurer to issue insurance policies with larger coverage limits or amounts than it would prudently issue on its own. If the insurer has no retention limit or it is set too high, the insurer runs the risk of insolvency if several large claims occur in a short period of time.

- Investment Risk Transfer. Insurers may reinsurance a block of business to effect a transfer of investment risk from the insurer. This can occur because of the growth of interest-sensitive life and annuity products to either take advantage of reinsurer asset management capabilities or to avoid a large concentration of assets arising from a single product or annuity.

- Financial Results Management. Insurers can utilize the financial reporting impact of reinsurance agreements to optimize the insurer’s earnings and surplus objectives and also to minimize taxes.

8.6 A mixture of both objectives can be achieved by reinsurance arrangements providing for:

- Gaining Product Expertise. Upon entering a new line of business, product or territory, an insurer may request the assistance of a reinsurer with existing experience in that market. In exchange for their advice, the reinsurer will participate via reinsurance in the future profitability of the business sold.

---

• Underwriting Advice. A benefit provided by reinsurers is their experience in underwriting. This can prove valuable during the design, pricing and underwriting of products, especially new, novel, large or complex ones.

• Divesting a Product Line. An insurer wishing to exit from a certain business, product or territory may choose to cede that business by means of an assumption reinsurance agreement or through indemnity reinsurance, thereby transferring a loss portfolio.

Finally, reinsurance is crucial to the viability of many, in particular smaller companies. Small or mono-line companies use reinsurance as a diversification and risk reduction tool, so that they can compete effectively against large diversified companies. Note that reinsurance protection is normally at the price of a reduction in the expected earnings of the cedant. This reduction of expected earnings reflects a “fair price” for the risk transfer. For many companies, buying reinsurance is a good economic decision despite the reduction in expected earnings. For them, the risk reduction from buying reinsurance may outweigh the economic cost of putting up the additional required capital.

8.2 Types of Reinsurance

8.8 Reinsurance covers typically have two different types: proportional or non-proportional. Proportional reinsurance covers are quota share of surplus covers, while non-proportional covers comprise excess of loss or stop loss contracts. Both types are often, mixed or aggregated.

8.9 A quota share cover assumes a contractually fixed percentage of each and every loss in exchange for the same percentage of premium income ceded by the insurer. This proportional mutual sharing of benefits as well as losses can be adjusted contractually through profit sharing such as sliding commissions and the like. In terms of risk mitigation, quota share reinsurance takes a fixed percentage of each and every loss, thereby simply “compressing” the risk profile. This means that the expected loss, or any percentile (such as the 99th percentile), reduces by the same percentage (i.e., the share ceded to the reinsurer). This is illustrated in the following exhibit.

Effect of Quota Share Reinsurance on Loss Distribution

8.10 Excess-of-loss reinsurance provides that for each and every loss amount exceeding a predefined threshold, the so-called priority or attachment point, (e.g., US$ 1 mill.) is covered by the reinsurer, up to a certain limit. Under an excess of loss cover with priority \( P \) and cover limit \( L \), the reinsurer assumes for each loss \( X \) incurred by the cedant:

\[
\text{Max} \left( 0 ; \text{Min} (X-P; L) \right)
\]
8.11 The effect of excess of loss reinsurance is that it truncates the loss distribution for the cedant at the priority, implying that any loss amount exceeding the priority will be assumed by the reinsurer, subject to not exceeding the limit per claim. This can be easily seen in the following exhibit, for an excess of loss treaty: the XL attaches in excess of 50 million. The net curve shows that there is zero probability of loss amounts higher than 50 million (unless losses exceed the limit) and therefore the distribution has a mass point at the priority. The gross loss distribution, however, extends well beyond 50 million with a 99th percentile at about 85 million.

**Effect of Excess of Loss Reinsurance on Loss Distribution**

![Effect of Excess of Loss Reinsurance on Loss Distribution](image)

8.12 Excess of loss reinsurance applies on an individual claims basis rather than on a portfolio basis like proportional contracts. Repeat coverage for more than one claim is usually achieved through refilling the coverage by paying reinstatement premiums. Excess of loss coverage is provided on a per event basis covering one or multiple claims arising from one and the same event, or on a per risk basis where the coverage applies to one risk independent on the event affecting the insured risk.

8.13 Most importantly, the reduction in the expected loss for the excess of loss contract is minimal compared to the corresponding mean reduction of the quota share. However, the risk reduction of the excess of loss contract (e.g., measured at the 99th percentile) is vastly higher at approximately 35 million, while the quota share reduces risk only by approximately 15 million, thereby demonstrating the different transformation characteristics of proportional versus non-proportional reinsurance contracts.

8.3 **Effect of Reinsurance on the Risk Profile**

8.14 As outlined in the preceding section, any analysis of a company’s risk profile (and therefore its capital requirement) is incomplete without proper treatments or recognition of its reinsurance arrangements. Reinsurance contracts typically have significant impacts on the company’s aggregate risk profile, usually with the effect of reducing risk, and thus are important considerations for the capital requirement of an insurance company.

8.15 The following graph illustrates the effect of risk reduction through reinsurance on the company’s results, the sum of premiums minus expenses and losses. While proportional reinsurance typically reduces the overall (nominal) risk in a linear way, non-proportional covers typically address the large losses, thereby reducing the company’s net exposure to large loss/catastrophic events. Technically speaking, non-proportional reinsurance eliminates part or all of the volatility coming from the tail of the distribution.
8.16 The probability distribution in the above graph shows how the 99\textsuperscript{th} percentile of the probability distribution of losses is shifted to the left, indicating a reduction in risk. Note in particular that the tail of the distribution is reduced materially, if not even eliminated.

8.17 Reinsurance, in particular the non-proportional type, can greatly reduce, or even eliminate, the extreme tail of the cedant’s loss distribution. This effect can be assessed mathematically if the TVaR risk measure is being used. On the other hand, the reduction in standard deviation (in the WP’s opinion this is an inferior risk measure for a capital requirement) can be disproportionately less. If applied properly in a solvency or management context, reinsurance is a very efficient means of reducing risk (particularly if measured by TVaR) and therefore risk-bearing capital. Reinsurance can therefore be a useful alternative for (solvency) capital.

8.18 Given the above discussions, it is obvious that a proper recognition of reinsurance is a must to assess the risk reduction for the ceding company with implications for its capital requirements in order to ensure effective supervision of insurance enterprises in relation to solvency and capital requirement.

8.4 Challenges in Assessing the Impact of Reinsurance on a Company’s Risk Profile

8.19 While proper treatments and recognition of reinsurance arrangements are necessary to assess the impact of the of a ceding company’s risk profile, this is a difficult task for a number of reasons.
8.20 The first complexity comes from the tremendous diversity in the types of reinsurance contracts:
- typical reinsurance arrangements comprise both proportional and non-proportional covers
- some contracts have variable rating terms, such as sliding scales or loss corridors for a proportional reinsurance treaty, and reinstatements or contingent commissions for an excess-of-loss treaty
- some contracts cover just one line of business, others cover multiple lines of business and others cover single loss events only
- some contracts are on an aggregate basis, with aggregate deductibles and aggregate limits
- some financial type reinsurance contracts cover a hybrid of underwriting and financial risks.

8.21 The second complexity comes from the fact that many reinsurance contracts do not bear a linear relationship with the underlying risks. For instance, there is a leverage effect of claim inflation on the loss costs of excess-of-loss covers. In fact, the contracts transforming the overall risk into a “narrower” risk profile typically are exactly of this nature. The magnitude of the leverage effect depends on the sizes of the retention (attachment point, or priority) and the limit\(^5\).

8.22 A properly structured reinsurance program can significantly reduce the cedant’s risk exposure and capital requirement. However, not all reinsurance warrants a reduction in the capital requirement, in particular when it is inadequate. This introduces the third complexity of reinsurance:
- If improperly designed, a reinsurance program may be inefficient in reducing the total risk of the cedant.
- Some reinsurance contracts do not contain significant risk transfer and are mainly used for some specific accounting or tax effect. For instance, U.S. statutory accounting does not allow immediate recognition of the equity in unearned premium reserves; this created incentives for some companies to purchase proportional reinsurance treaties with ceding commissions as a surplus relief. As another example, U.S. statutory accounting does not allow for discounting of loss reserves; this created incentives for some companies to purchase loss portfolio transfers to indirectly achieve the effect of loss reserve discounting.
- Some reinsurance contracts may have credit risk exposures, that is, the loss recoverable may be non-collectable in the cases of contract dispute or reinsurance failure\(^6\).

8.23 The fourth complexity lies in the fact that the reinsurance recoverable may be highly correlated with the cedant’s net risk exposures. This correlation may go beyond simple linear correlation for excess-of-loss treaties.

8.5 Implications for Recognition of Reinsurance in a Future Solvency System

8.24 The recognition of reinsurance for solvency purposes must be closely linked to the ability of the company, supervisor or both to assess the impact of the reinsurance program on the risk profile. Given the diversity and complexity of reinsurance contracts, it is apparent that a simple factor-based approach is likely to be too crude to reflect the effect of reinsurance on capital requirements accurately. Therefore, standardized (e.g. factor-based) approaches should be used with caution since the proper treatment of reinsurance really requires a modelling approach. Similarly, if the gross risk profile is not, or is only very vaguely described, the proper recognition of reinsurance in terms of risk reduction is not possible.

---

\(^5\) While many European countries use an index clause to stabilize the impact of reduction in the risk profile, the index clause is not commonly used in the U.S.

\(^6\) For a discussion on reinsurance credit risk, refer to section 5 and Appendix E

Copyright © 2004 International Actuarial Association
8.25 For the assessment of the reinsurance impact on the risk profile, there are two general methods of evaluating the amount of risk transfer in a reinsurance contract:

- judging the amount of risk transfer for a reinsurance contract by analyzing whether the cedant has transferred (reduced) risk, on an enterprise-wide basis
- judging the amount of risk transfer for a reinsurance contract by focusing on a stand-alone single transaction as defined in the contract.

8.26 According to the enterprise-wide approach, the impact of the entire reinsurance program on the risk profile needs to be evaluated. The assessment of individual contracts on a per risk or line of business basis, particularly of an excess of loss nature, is practically impossible. However, for proportional transactions, such as especially whole account quota shares, or stop loss, agreements can be evaluated on an approximate basis. For example, a whole account stop-loss limits the maximum downside of the underwriting result and thus, assuming the reinsurer performs, the maximum capital at risk can be quantified.

8.27 Except in the case of a stop-loss arrangement, a risk-based solvency assessment is impossible in the absence of reliable aggregate loss distribution data and exposure information. In this situation, a prudent supervisory approach would be to give no credit for the purchase of reinsurance.

8.28 This said, most companies have some exposure information for at least a few lines of business. Typically, property lines have at least exposure profiles and these can be used as a proxy. In addition, those profiles could be compared to industry data where available and blended to achieve a proxy for the company’s risk profile. Combining the profile of several lines in an additive manner, thereby not allowing for diversification effects and introducing a level of conservatism to the proxy, an approximate total company profile could be derived.

8.29 Provided that an adequate internal enterprise-wide risk model is available however, one can evaluate the effect of all reinsurance contracts in a consistent manner. Basically, one can use the internal model to evaluate the total capital requirement on a gross basis (without reflecting reinsurance), and then on a net basis (net of reinsurance). Presumably, the internal model can reflect all the intricacies of the reinsurance contract terms. The enterprise-wide method is desirable from a total balance-sheet modelling perspective. However, it can be quite a challenge to model all parts of an enterprise and their interactions properly.

8.30 In summary, in the absence of an internal enterprise-wide model the risk reduction relative to an expected shortfall measure is virtually impossible to quantify reliably, with the possible exception of a stop-loss arrangement, and in such circumstances the reinsurance credit should be minimal or not given at all.

8.31 For the assessment of the risk transfer under a particular reinsurance contract, one can perform the risk modelling of the cash flows between two parties based on the contract terms, without referring to a full enterprise-wide model. This can be a much more pragmatic method when a satisfactory enterprise-wide model is not available. In practice, many companies have adequate partial risk models describing the risk profile for some of their segments. This is particularly the case for property coverage.

8.32 In those cases, the risk characteristics can be described by segmenting the underlying contracts into homogenous “risk buckets” describing the exposure of the underlying risks in terms of insured value, retention, policy limit and maximum loss/PML, to name a few. This data can then be used to derive a gross risk profile of the portfolio to be insured using frequency and severity/expected loss information. These gross loss distributions can be used to adequately apply proportional reinsurance transactions including loss-sensitive features as appropriate. This said, the proper evaluation of the risk reducing impact of non-proportional reinsurance contracts

---

7 Refer to the case study for non-life insurance for a general approach to practically apply such a routine.
is still not possible without either relatively complex mathematical transformations, which are typically beyond the of supervisory control mechanisms, or the use of simulations, which are standard routines for more complex risk modelling in internal models.

8.33 Ultimately, the most adequate assessment of the risk transfer capability of a reinsurance contract or a combination of several contracts, is through the description of risk using detailed loss and exposure data. From this information, possibly blended with industry data, the company can derive specified and validated loss distributions. These gross distributions can then be fed into routines transforming gross simulated loss samples into a net distribution by applying the relevant reinsurance terms to each figure and aggregating the transformed simulations into a net outcome. While this approach is obviously laborious and more time-consuming than the other approaches outlined above, it more adequately and reliably describes the risk reduction achieved by reinsurance.

8.34 While the approach described above can be applied for each “risk bucket” (e.g., line of business), it does not resolve the aggregation of the individual risk profiles into a total company profile as this process would need to consider dependencies between risks, like concentration or diversification. A discussion of this issue, and possible solutions, are presented in the following sections of this report.

8.35 In summary, the WP concludes that the possibility to adequately reflect the risk reducing impact of reinsurance crucially depends on the ability to reliably come up with a risk profile of the portfolio to be reinsured. The less information is available and the cruder the model is, the less adequately the impact of reinsurance can be assessed, and consequently, the less credit should be given. Conversely, detailed and consistent risk information enabling a company to describe its risk profile properly (e.g., such as in an internal model - even if it is only for part of its business), allows the evaluation of the impact of reinsurance and the corresponding credit for the purpose of solvency assessment, to be given proper consideration by the supervisor.

8.6 Reinsurance Credit Risk

8.36 Reinsurance arrangements often generate a long-term relationship between cedant and reinsurer. The reinsurer typically collects premium at contract inception and remunerates for losses falling under the policy as they are reported and paid. Obviously, the stability of the relationship crucially depends on the ability to reliably come up with a risk profile of the reinsurer. Occasionally, reinsurance recoverables are not collectible as the reinsurer is either unable or unwilling to perform (i.e., when the reinsurer becomes insolvent or there is dispute regarding the coverage).

8.37 To recognize the credit risks on the reinsurance recoverable, a factor $\theta$ (say, $\theta = 70\%$) can be applied to the full amount of capital relief derived from having a reinsurance arrangement in place. The factor $\theta$ may vary depending upon

- the financial stability of the reinsurer (e.g., as expressed in quality rating)
- the amount of collateral being posted
- the nature of the reinsurance (i.e., short versus long tail)
- concentration risk (one reinsurer versus several)

8.38 The charge for reinsurance recoverable, $\theta$, should be in line with the charge for bond defaults with similar default frequencies
As a consequence, the net capital requirement for the ceding company after reinsurance can be derived very simply and is equal to (assuming a linear $\rho$):

$$\rho(X) - (1-\theta) \rho(X_{\text{cede}}) = \rho(X_{\text{net}}) + \theta \rho(X_{\text{cede}}).$$

Where $\rho$ denotes the risk measure applied (eg. Tail Value at Risk) and $X$ denotes the aggregate loss.
9. Total Company Requirement

9.1 Concentration

Concentration risk is the risk of having higher-than-normal relative risk exposure in a single risk. For example, investment of a high proportion of assets in a single economic sector might be considered concentration. In practice, concentration risk can result in a “penalty” in capital requirements; that is, more capital is required. Concentration is the opposite of diversification.

9.2 Diversification

Diversification reduces risk to the extent that less total relative capital is required when combining two risks. In practice, diversification benefits should be reflected in a capital formula to encourage insurers to have more diversified assets and liabilities.

9.3 Risk Dependencies

The risks an insurer faces often exhibit comovement or dependencies. This means that knowledge about results for one risk can be used to better predict the results of another risk. Dependence between two risks may be because there are known relationships between these two risks or simply because certain correlations or other relationships have been observed historically. Dependence can increase or decrease the capital required to support the combined two lines. If losses for one risk tend to increase as the losses for the other increases, there is a positive correlation, usually resulting in more capital required than if the two risks are mutually independent. Similarly, if one tends to increase as the other decreases, the two risks form natural hedges and usually require less capital. If an insurer builds an internal model, it needs to reflect the nature of all significant dependencies. Similarly, with factor-based models, the formula used to combine risks needs to reflect all significant dependencies.

9.4 As in previous sections, we consider the total risk to which an insurance company is exposed (e.g., stemming from its insurance operations, investment activities, currency movements, etc.). Typically, the risks to which a company is exposed are not independent, but rather have some, sometimes minor and often difficult to observe, interaction. In many cases and unlike to financial markets, there is very little historical data to detect and quantify the real relationship between risk factors. Hence, it may not be possible to identify all sources of interaction and build them into an internal model or even estimate their correlations or related measures of interactions.

9.5 The comovement of risks faced by an insurer can be the result of two general types of dependencies: structural or empirical. The structural comovements are due to known relationships, which can be accounted for in a modelling exercise; while empirical comovements are simply observed without any known (or capable of being modelled) relationships. Structural dependencies include situations where loss variables are driven by common variables. For example, economic factors like general economic inflation can drive costs in various lines of insurance in the same direction. Similarly, common events or “shocks” such as an automobile accident, can trigger several related claims (bodily injury, property damage, etc) simultaneously. Other common factors can drive losses in opposite directions. For example, improving mortality reduces costs for life insurance while increasing costs for life annuities.
9.6 In addition, the degree of dependency of insurance risks leading to comovement may increase in extreme outcomes of the risk. Actual examples in insurance include the catastrophes of September 11 affecting not only aviation insurance, but also property, business interruption, workers compensation, life, personal accident and several other lines of business. Similarly, it is easy and logical to imagine that major natural catastrophe, such as a California earthquake occurring on a weekday morning, would affect both property (catastrophe) insurance as well as workers compensation, lines of business that are typically regarded as largely independent (the company may also own property in a catastrophe area).

9.7 Structural dependencies can be modelled directly in internal models and reflected appropriately in factor-based formulas. This is illustrated in one of the case studies where the level of claims costs is determined by a common inflation risk factor. In this case, all claims will be larger if there is general inflation. The uncertainty about the level of claim amount (i.e., inflation) is the uncertain risk factor.

9.8 For many types of risks, particularly in property and liability areas, correlation in movements are observed, but may not be easily explained. In many cases, correlation may be understood by general reasoning, but may not be easily measured due to scarcity of data. This is especially the case for rare events, which may trigger various types of claims.

9.9 It is therefore necessary to find methods or models to describe dependencies both in the absence of reliable or scarce data as well as the increasing dependency in extreme events, i.e. in the tails of the probability distributions describing the risks. It may be possible to model dependencies directly if their nature is well understood. However, it is more likely necessary to construct dependency models that reflect observed and expected dependencies without formalizing the structure of those dependencies with cause-effect models. The theory of copulas provides a comprehensive modelling tool that can reflect dependencies in a very flexible way.

9.10 While structural dependencies are modelled directly in an internal model, empirical dependencies are most easily modelled using specific dependency models called copulas. Copulas describe the relationship between the quantiles of distributions of different risks. They can be selected in order to recognize so-called “tail dependencies” where dependencies only occur, or only appear, in extreme circumstances. Appendix I gives an overview of some technical aspects of dependency modelling using copulas.
Appendix A    Life Insurance Case Study

A.1 Introduction

1.1 This life insurance company case study has been prepared by the WP to illustrate some of the concepts discussed in this report. The main purpose of the case study is to describe calculations that a company might undertake in order to determine total solvency provisions for various risks, and to highlight some of the issues in these calculations.

1.2 The case study describes what might be considered an advanced approach, through the use of an internal company model to quantify the risks. Standardized approaches can be implemented as an approximation to the more advanced approaches, or as a minimum capital requirement, in the event that advanced internal modelling is not possible.

1.3 With this objective in mind, the ultimate goal of this case study is to illustrate some of the concepts for advanced internal modelling, and to highlight some of the issues that standardized approaches must address in their formulation.

1.4 The case study has been designed with a focus on advanced models because of the complex nature of the life insurance business relative to shorter duration businesses such as banking or non-life insurance. Generally, the risks facing life insurers are of long duration, and tend to have complex interactions between them. In addition, there are a wide variety of products and management practices in different jurisdictions around the world. Thirdly, it is difficult to find simple common risk metrics can be used in a standardized approach. It would be overly simplistic, for example, to use sum assured as a base to apply factors, because this does not reflect important risk factors such as age or sex. A basis such as premiums might reflect these risk factors but also introduce the company’s pricing philosophy in the local market into the equation, which would further complicate the factor development process. Another basis might be a prospective cash flow based valuation performed on a best estimate basis. This type of basis would again capture all the relevant risk factors, but introduces additional complexities such as what to do where the resulting liabilities are negative, or do not fit into the industry norms in some way (e.g., unusually large or small liabilities).

1.5 These characteristics make it difficult to create a simple standardized model that appropriately captures all risks across all jurisdictions. The starting point for developing a standardized approach in any particular jurisdiction would be to first understand how the risks behave using a more complex advanced model. This advanced model could then be simplified to arrive at a standardized approach.

1.6 There are two types of standardized models that could be conceived. The first could be described as a pure standardized approach, in which factors are developed that companies can apply to common exposure measures such as premiums, face amounts or liabilities. The second can be described as an assumption-based approach, in which capital is determined by re-valuing the liabilities using specified assumptions. In some situations, one approach might be preferable to the other. For example, it is possible to measure mortality volatility risks on a pure factor basis, because the risk is short-term in nature. Longer duration risks, such as mortality level risk, might be more appropriately capitalized using an assumption-based approach, in which the regulator requires capital based on the difference between liabilities established using a specified assumption and that assumption used in deriving the liabilities.

1.7 The remainder of this case study focuses on advanced modelling approaches, with some discussion of the approaches that might be taken to derive a standardized approach.
A.1.1 Advanced Approach (Internal Models)

1.8 In this case study, the advanced approach is defined as the product of an internal model to quantitier the various risks being considered. The general approach in this model considers each risk one by one, and quantifies the probability distribution of “liabilities”, that result from each risk being considered. The solvency requirement for a particular risk is derived from this distribution, such that there is a high probability that the actual liabilities will prove to be less than the solvency requirement, in respect of that particular risk. The resulting solvency requirements for each risk are then aggregated into a total company requirement, taking into account the correlation between the various risks.

1.9 It is important to note that the case study focuses on the total solvency provisions, without regard for the allocation of these solvency provisions between liabilities and capital. The focus is on the quantification of the total provision for risk that is needed to establish a high confidence that the risk will be provided for, without worrying about the specific accounting implications.

1.10 The liabilities are defined in these calculations as the present value of future liability cash flows, discounted at the risk-free rate. All of the assumptions used in projecting the liability cash flows are the Company’s best estimate of future experience, except for the assumption / risk that is being evaluated. For the risk being evaluated, the internal model varies the assumption and/or cash flows according to some underlying stochastic process, depending on the specific risk. This process generates scenarios in which the liabilities vary based only on the risk being measured. The probability distribution of liabilities is then tabulated, and the solvency provision is established.

1.11 Several specific points should be noted:

- The liabilities that are being modelled are defined on the basis of cash flows over a time horizon appropriate to the risk being modelled. With systematic (non-diversifiable) risks, such as misestimation of mortality parameters for example, the time horizon is the entire term of the liability. Non-systematic (diversifiable) risks, such as mortality volatility, are based on a 1-year horizon, which is the assumed length of time that a regulator requires to react to an adverse situation if necessary.

- The solvency provision for a particular risk is defined as the difference between the average liabilities that result under the worst 1% of scenarios, and the best estimate of liabilities. This is referred to as CTE (99) minus CTE (0), where CTE stands for “conditional tail expectation”. For the risks covered in this case study, this is approximately equivalent to establishing capital at the 99.5th percentile of liability outcomes.

A.1.2 Standardized Approaches

1.12 Standardized approaches are less complex than the advanced internal model approaches. Such approaches can perhaps better be characterized as “assumption based” systems with respect to the establishment of liabilities (i.e., reserves), and as largely “standardized” systems with respect to the establishment of required capital.

1.13 In Canada, for example, policy liabilities are defined on the basis of the statement value of assets exactly needed to mature the liabilities with no resulting surplus, under adverse liability and economic scenarios. In projecting the liabilities, the actuary has some discretion, within bounds, of risk-adjusting the liability cash flows. Because the liability cash flows for life companies generally extend well beyond the duration of currently existing assets, further assumptions must be made about the reinvestment of future cash flows and assets to meet those obligations. The general intent is to model the actual reinvestment strategy followed by the Company, under various future economic scenarios. The actuary must perform this calculation for a certain number of prescribed scenarios, and can optionally perform additional scenarios. The final
liability that the actuary reports must equal statement value of assets needed to mature the liabilities under at least the highest of the prescribed economic scenarios.

1.14 Having established liabilities as above, the Canadian Company will report surplus as the assets in excess of liabilities. This surplus must exceed certain “Minimum Capital” requirements by a margin of 150%. The Minimum Capital is generally the result of applying factors to exposure bases. For example, capital for asset default risk is the result of factors applied to book value of assets, while the capital for mortality risk is the result of factors applied to the net amount at risk.

1.15 The Canadian approach, as for most jurisdictions, is focussed on the allocation between liabilities and capital. Conceptually, some risks are provided for in the liabilities and not in capital, whereas other risks are provided within capital and not in the liabilities. For example, provisions for the misestimation or deterioration of the mortality assumptions, is entirely within the liabilities. By contrast, provisions for volatility and catastrophe are entirely covered by capital, and not by the liabilities.

1.16 It is worth noting that any standardized approach will not fully capture the characteristics of the risks being evaluated, and may in fact produce misleading results.

A.1.3 Risks Covered by Case Study

1.17 Provisions are established in the case study for the following risks. These are described in additional detail in the following sections:

**Mortality (Systematic Risks)**
- Misestimation of the mean, i.e., the risk that the assumed best estimate mortality assumption in the liability calculation is not the true best estimate (statistical error)
- Trend, i.e., the risk that future mortality deteriorates (or improves) relative to the current date, in a manner different than we expect in our best estimate

**Lapse (Systematic Risks)**
- Misestimation of the mean, i.e., the statistical error associated with establishing the best estimate lapse assumptions

**Non-Systematic Insurance Risks**
- Mortality volatility risk
- Catastrophe risk (mortality)
- Lapse volatility risk

**Market Risks**
- Credit risk on assets supporting both liabilities and surplus
- Mismatch risk, or ALM risk, associated with the cash flow mismatches between liabilities and associated assets

1.18 Additional risks can also be considered, but were not in this case study to keep our sample company relatively simple. Of these risks, the most significant is the lapse risk caused by policyholder behavior and in particular, its interaction with changes in economic variables. This is an area where more experience is needed in extreme economic environments. It is also one risk that is very difficult to reflect appropriately on a purely factor-driven basis.
A.2 The Insurance Company

2.1 The company (i.e., the Company) constructed for this case study can be described as a medium sized insurance company that offers relatively simple term and whole life insurance products to its generally diverse customer base. It has experienced steady, but growing, sales over the past 15 years. In addition, the Company issues an immediate annuity product to retirees. All products are issued on a non-participating basis, and the Company has no equity-linked or interest-sensitive products, such as universal life. A simplified insurer has been used to illustrate the basic concepts.

2.2 Assets are managed at the segment level, with separate segments existing for the insurance products, annuity products and surplus. The Company generally invests in high grade fixed income securities to support the liabilities, but is more aggressive with its surplus, investing in common and preferred stocks in addition to fixed income securities.

2.3 The case study assumes the Company has various reinsurance arrangements in place, on one of its product lines (see the section entitled “Reinsurance Considerations”). First, the Company is considered on a gross of reinsurance basis.

The chart below summarizes some of the key features of this company.

<table>

2.4 On a Canadian GAAP basis, the balance sheet of the Company at December 31, 2002 can be summarized in the following table:
A.3  Total Company Solvency Provisions

A.3.1  Summary of Total Company Provisions Using Internal Models

3.1  This section describes how an internal model might be used to quantify the various risks. First, the results of all of the calculations are summarized, then the details on each risk are explained. In each section, are presented some considerations in determining capital using standardized, or standardized, approaches.

3.2  The table below summarizes the solvency provisions generated by our internal model, for each risk/product type, and in aggregate at the Company level. Several points are worth mentioning or repeating. First, the figures in the table are the total solvency provision needed in addition to the best estimate liabilities. These figures are not estimates of the liabilities themselves, but estimates of the capital. Second, these are based on the present value of cash flows discounted at the risk-free rate, at the CTE 99 level. Third, not all risks have been quantified explicitly for each product segment. For market risk, the analysis was performed at the level at which the risk is managed, at the asset segment level. Finally, these capital provisions have been estimated separately for each type of risk and product. At the Company level, these separately determined provisions have been aggregated using methodologies described in section 3.1 “Risk Aggregation”.

</table>

3.3 In the table above, the total solvency provisions have been determined by assuming a matrix of correlations between types of risk and between products. The total solvency provisions result from the multiplication of these matrices.

A.3.2 Techniques to Aggregate Risk Provisions

3.4 There are several techniques that can be used to aggregate risks at the Company level. The most ideal solution, that is also the most difficult to achieve in practice, is to develop an internal model that reflects all correlations and dependencies between all risks and product types. The output of such a model would be total solvency provisions at the company level. With such a model, there is no need to make estimates or approximations about the manner in which risks are inter-related, rather there would be a need to develop approximate methods to reallocate the total capital requirements to the product/risk level. For most life companies, this approach is not feasible.

3.5 Another approach is to use copulas to aggregate the risks. As described elsewhere in this report, copulas are mathematical functions that describe the relationship between risks.

3.6 The approach taken in the case study is an analytic approximation, in which each risk and product is first modelled independently, and then simplified correlations between the risks are developed based on intuition, benchmarks and historical data where available. It was assumed that the economic capital for the combined distribution of all risks in Company could be approximated by the formula

\[ EC_r = \sum \sum EC_i \times EC_j \times \rho_{ij} \]

3.7 Where \( \rho_{ij} \) represents the correlation between risks \( i \) and \( j \), and \( EC_i \) and \( EC_j \) represents the amount of capital that has been determined for risks \( i \) and \( j \) on a stand-alone basis.

3.8 The first set of assumptions made relates to the correlations between products, given a particular risk being evaluated. For example, if mortality volatility risk is evaluated at a high confidence level such as the 99th percentile or higher, the subjective assumption might be made that each product is 25% correlated with each other. In other words, the assumption is made that extreme levels of volatility have some effects on all product lines. At lower confidence levels (i.e., under normal operating conditions), a different assumption might be made, such as that the volatility risk is independent across product lines. The specific assumptions used are shown in the table below. Note that no assumption need be made for market risk (credit risk and mismatch risk) because these are modelled at the company or segment level. Note also that a simplifying
assumption is made that each product is correlated in the same way, for a given risk. For example, all products are 25% correlated with each other with respect to the mortality level uncertainty risk. If a more complicated assumption is desired (e.g., perhaps different products have different degrees of correlation), then it would be necessary to create a separate covariance matrix for each risk type.

<table>
<thead>
<tr>
<th>Risk</th>
<th>Correlation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mortality level uncertainty</td>
<td>25%</td>
</tr>
<tr>
<td>Mortality trend uncertainty</td>
<td>100%</td>
</tr>
<tr>
<td>Mortality volatility</td>
<td>25%</td>

<td>100%</td>
</tr>
<tr>
<td>Lapse level uncertainty</td>
<td>50%</td>
</tr>
<tr>
<td>Lapse volatility</td>
<td>50%</td>
</tr>
</tbody>
</table>

3.9 Application of these correlations to the separately determined economic capital figures gives the combined capital measure for all products, given a particular risk type.

3.10 Next, we make an assumption about the degree to which the risks themselves are correlated. This is shown in the following table:

<table>
<thead>
<tr>
<th>Risk Correlations</th>

<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

3.11 For example, it might be assumed that mortality volatility risk is weakly (25%) correlated with mortality level uncertainty risk, reflecting the fact that estimates of future mortality levels are at least partially based on historical observed mortality, which is volatile.

3.12 The combined company level capital is then determined by applying this covariance table to the matrix of capital determined for each risk type.
A.4  Solvency Provisions for Mortality Risk

A.4.1  Mortality Level Risk (Misestimation of the Mean)

A.4.1.1  Internal Model

4.1  The Company derives best estimate mortality assumptions for each product segment in the portfolio. These best estimates are based on mortality studies, which are assumed to be derived from the same portfolio being evaluated. In practice, smaller portfolios would not rely entirely on their own experience data in establishing a mortality assumption. It is assumed that the mortality study has resulted in the creation of a mortality table that varies by age, duration and calendar year.

4.2  The mortality study is based on observations that, by nature, are volatile. The more volatile the observations, the higher the uncertainty in the underlying level of mortality assumption. Higher uncertainty can arise in smaller portfolios as well as in portfolios that are highly skewed in their distribution of insured amounts.

4.3  In doing a mortality study, it is presumed that the historical observations represent the best estimate level of mortality. It is possible however, that the observations are not a best estimate, but are somewhere in the tail of the true distribution. By assuming that the observations were actually at, say, the 95th percentile of the true distribution, the implied best estimate assumption can be solved for that could have resulted in such an observation. This can be done using an inverse Normal Power approximation or as an approximation, by simulating the claims experience of the underlying portfolio for the same period of time as the length of the mortality study, and observing the 95th percentile of that distribution.

4.4  The approach taken in this case study is in fact to determine the mortality assumption that would be needed at several percentiles of confidence, using the Normal Power approximation. The liabilities are revalued under each of these assumptions, keeping all other assumptions at the best estimate level. The table below illustrates the range in possible mortality assumptions that result. In all cases, the Company’s best estimate of future mortality is 70% of the industry table, and what is being measured is the degree to which this best estimate could be wrong. From this table, it can be seen that the smaller the portfolio, the larger the range of possible outcomes for future mortality. In practice, a company might also partially rely on industry data using credibility theory. This adds an additional level of misestimation risk into the process that has not been considered here. It has been assumed that the Company sets mortality based solely on its own results.

</table>

4.5 For example, at the 50th percentile, the mortality assumption being tested is approximately 70% of the Industry table (71% in the case of ALC 1002). Note that the 50th percentile is not necessarily equal to the best estimate of 70% because of skewness in the portfolio. At the 95th percentile of confidence, the liabilities would be recalculated using 80% of the table for ALC 1001, and only 77% for ALC 1003.

4.6 The liabilities are revalued at these (and additional) percentiles and a range of possible liability results are derived. In the model, a statistical distribution of the liabilities is determined that best fit the liabilities at the percentiles that have been explicitly calculated. This is done so that the distribution of liabilities can be filled out and the results aggregated with other risks and/or product types if desired. It is not strictly necessary to do this, if all one was concerned about was the liability at a high confidence level for that particular product and risk. For example, the liabilities could have simply been revalued at the 99.5th percentile of assumptions, and the difference taken between this and the best estimate liability as the solvency capital for this risk. In effect, this is being done in our case study as well, except that the rest of the distribution is being filled out.
4.7 The table below shows the results of this process.

</tbody>
</table>

4.8 Capital is determined as the CTE (99) less the CTE (0), or best estimate liabilities. For example, ALC 1001 has a best estimate liability of 157.2 million at an assumption of 70% of the mortality table. At the 99.9th percentile, however, which is 86% of the table, the corresponding liability is 204.2 million. Capital is based on the average of all liabilities in excess of the 99th percentile.

4.9 Two other points are worth making:

1. The liabilities for two of the product lines are in fact negative. These two lines are the 1 year and 5 year renewable term liabilities, which are generally profitable at all ages and durations. As such, the premiums exceed the claim and expense amounts by a significant margin, and the corresponding present value of net liability cash flows is negative. If the company adopts a fair value, or cash flow based valuation system, then these negative reserves represent future profits that are being front-ended. In spite of this, the solvency capital is a positive number, because revaluing the liabilities under a more adverse mortality assumption results in a higher (i.e., less negative) liability.

2. For the annuity line (ALC 1007), the liability amounts decrease with increasing percentiles. This is because the percentiles measure the mortality assumption, and not the corresponding liability amount. For example, the 99th percentile liability figures shown in the table correspond to mortality assumptions at the 99th percentile of possible assumptions (i.e., in excess of the mean), based on the Normal Power approach described above. For some product lines, this results in an increased liability, whereas for other product lines, this results in lower liabilities with higher mortality. Products such as this offer some natural hedging of this risk for the Company.
A.4.1.2 Considerations for Standardized Approaches

4.10 Level uncertainty risk is an example where an “assumption based” approach would be more appropriate than a pure factor-based approach. For example, one possible approach would involve quantifying the liabilities on two bases: (1) best estimate mortality; and (2) mortality at a more conservative level, where the specific assumption would be a multiple of the best estimate assumption (100% plus a number of standard deviations, based on the confidence level desired).

4.11 To apply this method, the regulator would prescribe only a confidence level requirement, such as CTE(99), which can reasonably be approximated as the 99.5th percentile for most mortality risks. It would be up to each company to estimate the standard deviation of annual claims that can be expected from its specific portfolios, and to determine the more conservative mortality assumption to use.

4.12 A more restrictive approach might be to prescribe the additional mortality itself, rather than simply prescribing the confidence level. For example, the regulator might prescribe a solvency level of mortality as the best estimate plus a constant divided by the expectation of life. The constant to be added might vary from a low to a high range, depending on characteristics of the portfolio, such as credibility or homogeneity. Alternatively, the constant might not vary with the expectation of life, but simply be a flat additional percentage of mortality that applies to all ages. These constant factors would need to be sufficiently conservative to capitalize typical companies in the jurisdiction. In other words, in deriving the constant additional mortality, the regulator would be making an implicit assumption about the risk profile / standard deviation of portfolios in the jurisdiction, and testing the capital factors against this profile.

4.13 A “pure” factor-based approach would be the next step in this development, but would have to be developed with caution. Under this approach, the regulator would determine the capital using the assumption-based approach as above, but would express the capital as a percentage of an exposure base. The challenge is to develop an appropriate exposure base.

4.14 Consider this hypothetical example, in which the regulator has developed factors to be applied to “best estimate liabilities”, being the present value of future liability cash flows using best estimate assumptions. These factors have been developed using “typical” portfolios in the jurisdiction. The table below illustrates both the assumption-based approach and the factor-based approach. In the assumption-based approach, the best estimate liabilities would be revalued using revised mortality assumptions as a percentage of best estimate mortality, where the factors vary based on the risk profile of the portfolio. In the factor-based approach, we apply the factors in the table below to the best estimate liability itself. Here, the factors would also have to vary by product type, or some other measure that captures the characteristics of the underlying cash flows (e.g., duration). For example, a portfolio of annual renewable term insurance (T1), whose risk profile was 0.05 standard deviations per average claim, could determine the total solvency provision under the assumption based approach by valuing the liability at 107% of best estimate mortality. Under the factor-based approach, total solvency provisions equal to 140% of the best estimate liability could be established.

4.15 For the Company, the assumption-based approach is essentially equal to the internal model approach, given that the assumption-based approach was set using the same approach as the internal model. The factor-based approach, however, produces dramatically different results, because the portfolios in the Company are different from the portfolios by which the factors were developed. This highlights the reason why the use of best estimate liability as an exposure base against which to apply factors could be problematic.

A.4.2 Mortality Trend Risk (Deterioration of the Mean)

A.4.2.1 Internal Model

4.16 An important part of the best estimate mortality is the trend. The significance of the trend assumption in establishing a liability is influenced by the remaining duration of the portfolio, (and any periods for which mortality is guaranteed, for example through reinsurance, or through guaranteed annuity payments).

4.17 The “best estimate trend” can be estimated based on observations in the past, sometimes including expert opinions. The resulting trend will of course be uncertain. This uncertainty can be split into two parts. The first part exists because of the fact that the observations from the past will have been volatile. This volatility (movement around a certain level) will also exist in the future. The second part of the uncertainty trend is caused by systematic changes in the trend, for example due to medical developments, new diseases (like AIDS), and environmental changes. This uncertainty will increase looking further in the future.

4.18 Mortality rates are highly correlated between various ages and genders. The development of mortality rates is correlated between ages and genders. The degree of correlation itself varies over time. For this reason, it would be highly speculative to put forward a model that tries to directly estimate future mortality rates, as this would require too many assumptions. Instead, we would ideally like to indirectly quantify trend uncertainty by revaluing the liabilities using historically observed trend assumption tables. Analyzing the impact on the liabilities of the several variants of the trends observed in the past can give us an idea of the uncertainty trend. The impact of the correlation between ages, gender will be automatically included in the analyses. Generational mortality tables with trend assumptions built in to their construction can be useful.
4.19 An important factor in these analyses is the duration of the trends being reviewed. For an insurance portfolio with a remaining duration of \( n \) years we have to analyse what can happen with the trend over a period of \( n \) years. To do this, we observe as many historical trends with the same duration as the data will allow. Each of these trends can be used to recalculate the liabilities.

4.20 It is quite possible that sufficient historical observations do not exist, and that if they do exist, they do not capture the spectrum of possible outcomes. In Canada, for example, such data would be quite limited.

4.21 For illustrative purposes in this case study, a range of possible trend outcomes is captured by speculating that the annual rate of mortality improvement is normally distributed with a mean and standard deviation of 0.50% improvement per year, which is broadly consistent with mortality improvements in the general population over the past decade. Further the years of mortality improvement has been limited to 40 years, and also the maximum and minimum improvement assumptions to 3% per year. Using this, a range of scenarios of future mortality assumptions can be derived for revaluing the liabilities. As with the level uncertainty approach, this provides a distribution of possible liability figures, in which only the future trend is varied. All other assumptions are at the best estimate level.

4.22 The capital needed can be based on a \( p\% \) confidence interval from a Student-t distribution with \( n-1 \) degrees of freedom, if one is performing the calculation of capital based on revaluing the liability under \( n \) historically observed scenarios. Alternatively, if one is using a model to hypothesize future mortality improvement, then the capital can be established by revaluing the liability under a mortality improvement assumption that arises at various percentiles, and choosing the average of the largest 1% of liabilities, less the best estimate. It is important to recognize the subjective nature of either approach.

4.23 The table below illustrates the scenarios that were selected for testing. A particular scenario is assumed to apply to all products simultaneously, regardless of the effect of the assumption on the liability. For example, when we test a scenario that features a high rate of future mortality improvement, the effect is generally to produce lower liabilities for the insurance products, and higher liabilities for the annuity products. While one would normally expect an insurance portfolio to benefit from mortality improvements, this relationship can be reversed under certain reinsurance arrangements. This is illustrated further in the section on reinsurance.
At the total company level, the risk exposure to trend uncertainty can be dampened or magnified, depending on the product mix of the company. An internal model can recognize these interactive effects, but this is difficult to achieve in a standardized approach, which might, for example, require that capital be determined separately for each product and the results simply added up. This type of approach might be overly conservative as it assumes that different mortality scenarios occur for different product types.

Note that from the above table, the overall average mortality improvement is 0.50% per year, for 40 years, regardless of the product type. This figure results from the relatively simplistic model that future mortality improvements are selected from a normal distribution, modified only for maximums and minimums. The 0.50% best estimate improvement itself is roughly consistent with observed mortality improvements, in aggregate, in some countries. As mortality has been generally improving over the past century, we do not have many observations in which negative trend, or deterioration, has occurred. Our model implicitly assumes that the observed levels of mortality improvement will continue into the future, which may not be true. A higher standard deviation has been selected to adjust for this so that at higher percentiles, we may get some deterioration that has not necessarily been observed in the past. Capital would then be established at this adverse assumption. For example, at the 99.5th percentile, we are effectively establishing capital on the assumption that mortality will deteriorate by 0.76% per year. This has the effect of increasing insurance liabilities, but decreasing annuity liabilities. If the company had a larger proportion of annuities than insurance, then it may be that the capital is effectively established on the assumption of mortality improvement of 1.77% per year, as opposed to a worsening. A company using an internal model approach should be careful to apply some judgement on the resulting scenarios, to ensure that the assumed mortality improvement / deterioration is not unreasonable.
4.26 The liabilities that result from this work is shown in the following table:

CTE99 - CTE0 50.1 17.4 163.6 37.6 5.8 8.7 262.5

4.27 What is worth noting in this table is the total capital for this risk for the company is 262.5 million, when modelled in the aggregate assuming that the risk is 100% correlated by product, whereas the simple sum of capital requirements for each product (not shown in table) is $283.2 million. The annuity product, ALC 1007, has the effect of lowering capital requirements by approximately $20 million in aggregate, because it reacts favorably to adverse trend assumptions. This can be seen also by looking at the results by percentile. The insurance products (ALC 1001 to ALC 1005) all increase in liabilities at higher percentiles (i.e., at increasingly adverse mortality worsening), whereas the annuity liabilities decrease at higher percentiles. In the section on reinsurance, it will be shown that this effect is in fact amplified in a particular reinsurance situation. When modelling a mixed book of annuities and insurance products it may be wise to consider “non-parallel” shifts (i.e., using asset/liability – ALM – terminology) in mortality (e.g. by age or gender) to recognize the risk that mortality trend may not be perfectly hedged between the annuity and insurance books of business.

A.4.2.2 Considerations for Standardized Approaches

4.28 There are several possible ways to develop standardized capital models for trend. One example of an “assumption-based” method is to establish a total solvency provision based on a conservative estimate of trend. The difference between the liability established using this conservative estimate, and the liability established using the true best estimate, could be considered the capital for trend uncertainty. For example, the solvency provision for an insurance portfolio might be based on an assumption of no future trend improvement, compared to a best estimate trend assumption of 0.50% improvement per year. Annuity lines would require a solvency provision based on future trends greater than the best estimate.

4.29 A simplified approach to provide for trend uncertainty could be to apply a factor multiplied by the present value amount of the liabilities (see following formula). The factor might be expressed as the lesser of \( \alpha \) and \( \beta \) times the product duration \( n \). Some sample values of \( \alpha \) and \( \beta \) are also given in the table below.
\[ c_{\text{trend}} = \min\{\alpha, \beta n\}(\text{liability}) \]

<table>

</tbody>
</table>

The uncertainty trend for a whole life annuity can be based on 4\% of the liabilities (x>55). These calculations of trend uncertainty are based on a 99.5\% confidence level.

A.4.3 Volatility

A.4.3.1 Internal Model

4.30 Volatility risk, or process risk, is the risk that cashflows will not occur as expected due to statistical fluctuations around the expected assumptions. In quantifying this risk, we assume that we have indeed selected the correct best estimate mortality assumptions and future trend assumptions, and that we are only concerned with volatility given those assumptions.

4.31 Another important consideration is the time horizon, as described earlier. With the systematic risks, we wanted to provide for adverse liability cash flows for the entire term of the liability, because we cannot perform management or regulatory action to eliminate this risk. With diversifiable risks, however, such as volatility, we only project out for a 2 year time horizon, on the rationale that this risk can be managed. Our case study is therefore based on this 2 year time horizon with respect to volatility risk. As an illustration, we also show what the volatility capital would look like if we considered the time horizon to the full term of the liability. In aggregate, as one might expect, the resulting capital is larger when considering the larger time horizon, but the relationship between the 2 year and full term time horizons are not clear, and in some specific product cases, the 2 year horizon actually produces almost the same capital requirements as with the full term. This is because over the full term of the liability, time diversification is also occurring. Adverse mortality in the earlier years is ultimately followed by more favorable mortality in the later years, and partially offsets the adverse effect of the adverse mortality in the early years.

4.32 This case study has used a simulation approach, although analytic approaches are feasible to quantify volatility risk. Under the simulation approach, a Monte Carlo simulation of the portfolio was performed, with the intention of measuring either 2 years worth of claims or the present value of all liability cash flows to the full term of the liability (depending on the definition of volatility risk that we are exploring). The simulation is binomial, meaning that each person in the portfolio is simulated to live or die, based on an expected mortality equal to the best estimate assumption. The capital required is the difference between the claims (or liability) at TVaR_{99\%} and the best estimate claims (or liability) over that same period.

A. Volatility Based on 2 Years Claims

4.33 The table below illustrates the results for the various products assuming that the volatility of claims is measured over a 2 year horizon. The effect of aggregating these capital requirements under two extreme assumptions is shown: the volatility risk is 100\% correlated across each products; and the volatility risk is completely independent. It can be argued that the volatility risk is more likely to be uncorrelated, or only weakly correlated at extreme confidence levels, but for illustration purposes, both extremes are shown.

<td>121.0%</td>
</tr>
</tbody>
</table>

4.34 In aggregate, the capital is between 22.7 million and 31.7 million, depending on whether it is assumed that the volatility risk is correlated or not.

4.35 It is also worth noting that the capital as a percentage of expected claims is much higher for smaller or more skewed product distributions. For example, the largest capital requirements of $21.5 million (or almost 2 years worth of annual claims in this case), arises with product ALC 1004, which as the reader will recall, has only 7400 lives in the portfolio, and a wide range of sum assured in the portfolio. By contrast, product ALC 1003 has 95,000 lives and a more stable sum assured distribution, and the resulting capital requirements in this case are only 9.5 million, or 4 months of claims.

4.36 Related to this is the observation that for volatile products such as ALC 1004, the amount of claims increases in extreme measures at the tail of the distribution, relative to the other products. For example, the difference between claims at the 99.5th percentile versus the 99.9th percentile is an increase from $37 million to $54 million, which is a 50% increase. This type of jump is not seen in the other, more stable products.

4.37 Finally, under this approach, we attribute virtually no capital to the annuity lines (ALC 1007), as the impact of volatile mortality over a 2 year period on the monthly payments to annuitants (approximately $44 million over 2 years) is negligible.

B. Volatility Based on Present Value of Liability Cash Flows

4.38 The table below shows the capital that would result if we defined the capital based on the liability, or present value of future cash flows at the risk free rate. Generally, we see that the more volatile the product (for example, higher standard deviation of annual claims), the closer the capital requirements become regardless of the time horizon. ALC 1004 in particular, which we identified previously as the most volatile product, has virtually the same capital requirements regardless of the choice of definition. Large stable segments such as ALC 1003 would produce almost double the capital requirements, should the definition of capital be based on all liability cash flows. Also, under the full liability term definition, we do get capital requirements for the annuity product (ALC 1007), as volatility does affect the ultimate results in the long run. This is
perhaps appropriate for annuity type products, as it is arguable whether volatility risk for these products can be managed as easily as the insurance volatility risks.

#### A.4.3.2 Considerations for Standardized Approaches

4.39 Traditional volatility risk is often calculated using a simulation model. A good alternative is an analytical approach, such as the Normal Power approximation which uses the first 3 moments of the Compound Poisson distribution. Under this approach, the capital at a 99.5% confidence level in the Normal Power approach is:

\[ C_{vol} = \sigma(2.58 + 0.94\gamma) \]

In other words, the capital would be a multiple of the standard deviation of annual death claims, with an adjustment for the skewness of the portfolio.

4.40 The table below compares these simplified standardized approach to the internal model results.

<table>
<thead>
<tr>
<th></th>
<th>Internal Model</th>
<th>Normal Power</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALC1001</td>
<td>3.4</td>
<td>3.2</td>
</tr>
<tr>
<td>ALC1002</td>
<td>3.3</td>
<td>3.2</td>
</tr>
<tr>
<td>ALC1003</td>
<td>9.5</td>
<td>9.1</td>
</tr>
<tr>
<td>ALC1004</td>
<td>21.5</td>
<td>30.9</td>
</tr>
<tr>
<td>ALC1005</td>
<td>3.9</td>
<td>3.7</td>
</tr>
</tbody>
</table>

As the table shows, the Normal Power method produces reasonably accurate approximations to the internal model, except for product ALC 1004, which as the reader will recall is a highly skewed portfolio with a large standard deviation.

#### A.4.4 Catastrophe Risk

4.41 This risk can be described as the risk that a catastrophe occurs that causes a one-time spike in mortality experience, with a corresponding impact on claims and/or liabilities. As there have not been many observed catastrophes that affect insured life populations in the past century or so, it is difficult, and perhaps spuriously accurate, to formulate a model that quantifies this. Any such model would be highly subjective, and we expect that the industry may start focusing on this item. Such a model would most likely be a frequency / severity model that assumes probabilities of various types of catastrophes that vary by severity in their impact. For example, there might be a very small probability of an epidemic such as the Spanish Flu of 1918, that caused a doubling of
infectious disease mortality in certain age groups, and a larger probability of a less severe epidemic or other incident.

4.42 We have not attempted to model this in this case study. Rather, we have taken a deterministic approach. Under this approach, we require that the company have enough capital to absorb a doubling of mortality in a 1-year period. (Our model specifically assumes that although the event that causes the doubling of mortality occurs in the first year, the actual mortality impact is spread over a 2-year period as 50% increases in the mortality rate in each of those 2 years).

4.43 Because there is interaction between the catastrophe and the volatility risk described above, we want to consider the impact of both of these risks occurring simultaneously. To that end, we quantified the volatility risk using the Monte Carlo simulation described in the volatility section, and assuming that the expected mortality was double our best estimate mortality in the first year. We then measure the claims over a 2 year period (or the liability, depending on our definition of capital), at the CTE (99) level as well as the best estimate level. The total solvency requirement for volatility and capital combined is the CTE (99) figure at this higher level of mortality, less the CTE (0) figure using our best estimate of mortality (i.e., before the catastrophe). We attribute the volatility component of this capital as based on our best estimate of mortality, and the catastrophic component is the incremental difference in CTE (99) at the higher mortality relative to the CTE (99) at the best estimate mortality.

A. Catastrophe Based on 2 Years Claims

4.44 When we define the capital to be based on claims over a 2 year period only, this approach effectively amounts to a requirement equal to 1 years worth of claims, less an adjustment for the interaction between normal volatility risk and catastrophe risk. As the table below illustrates, for large and stable portfolios, the catastrophe risk is significant relative to the volatility risk, whereas for small and skewed portfolios, the catastrophe risk is almost indistinguishable from normal volatility.

B. Catastrophe Risk Based on Present Value of Liability Cash Flows

For information purposes, we show below the capital that would result under a doubling of mortality in the first year, as above, but where the capital is based on the present value of all future liability cash flows.

Under this definition, the relative magnitudes of catastrophe versus volatility have changed, with catastrophe not being as significant a component. Over time, the effects of the catastrophe become indistinguishable relative to volatility. In aggregate, the capital requirements are larger under this definition.
A.5  Solvency Provisions for Lapse risk

A.5.1  Lapse Level Risk (Misestimation of the Mean)

A.5.1.1  Internal Models

5.1  The lapse risk can be analyzed in a similar fashion to the mortality risk, although there are several other factors that need to be considered. In our case study, we have not dealt with these more complicated factors. It is a fair statement that significantly more work needs to be done by the actuarial profession in general to truly understand the lapse risk. Some of these factors include:

1.  A need to differentiate between those portfolios whose lapse rates are likely to show dependencies with other economic assumptions, from those portfolios that are not sensitive to economic conditions. Where the lapse rate does interact with other assumptions, the model should ideally reflect these dependencies. Such a model would be highly subjective, as there is little historical data to base this on. Even the form of the model would, at first, be speculative.

2.  The lapse assumption is highly dependent on the product itself, including the manner in which the product was sold, the competitive environment at the time of sale, the purpose of the product (eg, tax planning, insurance needs, etc). Even if the lapse assumption is based on large volumes of data, it is more difficult to apply those same lapse assumptions to portfolios other than the portfolio from which the lapse rates were derived. This increases the uncertainty around the lapse assumption significantly.

3.  The impact to the company of higher or lower than expected lapses can be positive or negative for different policy durations and product types. These relationships can change over time, not only with the natural aging of the policy, but also in the events that the other actuarial assumptions change in the future. This is further complicated by the potential impact of policyholder behavior.

4.  In addition to these, we also have the normal statistical error associated with estimating average rates from historical, volatile assumptions.

5.2  Our case study considers the last of these issues, the possibility that the best estimate lapse assumption, which is based on historical data for the company, is inaccurate due to statistical error.

5.3  To determine the statistical error in the lapse rates, we first analyze the lapse study that exists for the various product lines. These lapse studies give us, for each issue year within a product group, the actual lapse rates experienced by that cohort for several calendar years. From this, we determine our best estimate lapses as well as the standard deviations of those lapse rates. We make the assumption that the lapses are normally distributed, and we solve for lapse rates at alternate percentiles for each duration. For example, the best estimate lapse rate might be 10% in the first policy duration and grade to an ultimate lapse rate of 1% in 12 years. The corresponding lapse assumption at the 90th percentile might begin at 12.4% and grade to an ultimate of 1.2%. At the 10th percentile, the lapse assumption starts at 8.7% and grades to an ultimate of 0.8%. This effectively results in parallel shifts in lapse rate curves, although the degree of the shift varies by duration based on the standard deviations of the lapse rates.

5.4  Liabilities are recalculated using these various lapse assumptions, and from these deterministic scenarios, a distribution of liability amounts is fitted using statistical techniques. We do this so that we can fill out the distribution and combine with other risks if desired.
5.5 Of course, it is possible that the statistical error in the lapse rates is not always one-sided. In other words, it may be that the lapse rate for duration 1 might be overstated while the lapse rate for duration 7 is understated. By shocking the lapse rates in parallel by duration, we are assuming 100% correlation between the durations, which we assume will produce more conservative results than considering the lapse rates by duration as independent. We validate this assumption in our case study by performing some additional tests in which the lapse shocks do vary by duration. This may not always be appropriate, but in our case study, our approach turns out to be more conservative in the majority of scenarios tested.

5.6 We observe several things from this table:

- The liabilities for products ALC 1001 to ALC 1003 all increase with decreasing lapse rates, whereas the liabilities for products ALC 1004 and ALC 1005 do the opposite. These latter products are highly profitable renewable term policies in which the premiums significantly exceed the claims and expenses at most or all durations. Lower lapse rates than expected for these products help the Company because it results in unexpected future profits. By contrast, the first three products have level premiums which are ultimately insufficient in and of themselves to pay for claims. The Company in these cases is better off with higher lapses in those later durations.

- Three of the products are exposed to lower lapse rates, and two of the products to higher lapse rates. When combining the capital from these different products, we must make an assumption about the degree to which they are correlated.
  - On the one extreme, we could take the view that the lapse risks for each product is completely independent. That is, we may have underestimated the lapse rates for one product but overstated them for another product. If we combine the risks using this assumption, we get total capital requirements of $115 million, which can be approximated by the square root of the sum of the squares of the individual capital requirements.
We could also take the view that there is a systematic bias inherent in the lapse studies themselves, and that the lapse assumptions are therefore 100% correlated. For example, if we assume that all of the lapse studies for each product is done in the same corporate area using the same methodology, there may be a bias that causes the resulting lapse assumptions to be higher or lower than the true best estimate, for all products. If we aggregated the liabilities at the company level using this assumption, we would get aggregate capital requirements of $97 million. This is less than the capital that results from an assumption of independence between the products, because of synergies between the products. Higher liabilities arising from some product lines are offset partially by lower liabilities from other product lines in the same scenario.

Finally, on the other extreme, we could assume 100% correlation between the liabilities themselves. This would mean that we pick adverse scenarios that vary by product. For products ALC 1001 to 1003, we would be setting capital assuming very low lapse rates, whereas with ALC 1004 and 1005, we would be assuming high lapse rates.

A final consideration is that we could account for the risks that we have not modelled either by selecting a higher confidence level to set capital, or perhaps to set the final capital levels using multiples of capital derived by considering the statistical error risk only. We have not done this in our case study, but is the type of approximation we would consider in a real situation.

A.5.1.2 Considerations for Standardized Approaches

There are two primary effects of unanticipated lapse rates. The first involves the payment of surrender or termination values. The relationship of the amount of a surrender payment to the value of the liability being held in respect of a particular policy is of great importance. When a policy lapses, the company pays the surrender value and ‘receives’ the actuarial reserve that is released by the policy’s termination. If surrender values are lower than policy reserves, the company is at risk from lapse rates that are lower than expected, particularly if high lapse rates were anticipated in the pricing of a product. The case that surrender values exceed policy reserves results in higher lapse rates being unfavourable to the insurer. In some jurisdictions these risks are mitigated by regulations. A requirement that a company holds policy liabilities at least as large as surrender values provides partial protection against overly high lapse rates while minimum required surrender values reduce the likelihood that insurers will price their products using an assumption of high lapse rates. It is important to recognize that the relationship between the surrender value and the actuarial reserve is not fixed; it will generally vary with the duration of a particular policy.

The second primary effect of unanticipated lapse rates is that the insurer may not realise the expected recovery from future premiums of initial policy acquisition expenses. These acquisition expenses may be recognized implicitly in financial statements through the use of modified net level premium valuation methods. These implicit methods generally do not include any provision for unfavourable variations in lapse rates. Recovery of acquisition expenses may also be recognized explicitly through a reduction in policy liabilities or through introduction of a receivable asset. In this latter case, the adjustment to financial values is made subject to a form of recoverability test. Under the second primary effect, the risk to insurers is generated by lapse rates that are greater than expected.

Unanticipated lapses can have other effects on the financial condition of an insurance company. For example, anti-selective lapse by healthier lives may lead to deterioration in a life insurer’s mortality experience. This risk may be exacerbated by poor product design, an operational risk. In general, this risk is not treated for capital purposes as a lapse risk.
5.11 In the case that lapses are recognized explicitly in the valuation of actuarial liabilities, an approach to capital requirements in respect of the first type of lapse risk is available. This requires the division of policies into two classes: 1) those for which an increase in lapse rates results in an increase in policy liabilities, and 2) those for which policy liabilities increase when assumed lapses decrease. The capital requirement is of the form of the difference between a special valuation of policy liabilities and the normal valuation. For the special valuation, the lapse assumption is multiplied by a specified factor greater than one for policies in the first class and by a factor less than one for policies in the second class. As an example, in Canada, lapse rates are doubled for policies in the first class and reduced by one-half for those in the second class.

A.5.2 Volatility

5.12 Analogous to mortality volatility, this risk provides for uncertainty in cash flows arising due to statistical fluctuation around the best estimate lapse assumptions. This component can also be defined on the basis of either the impact on cash flows over a short term horizon such as 2 years, or as the impact on the liability, or present value of cash flows, over the entire term of the liability. Although process risk generally can be considered diversifiable, it is more difficult for a company to manage its volatility due to lapses as opposed to mortality. For that reason, it may be appropriate to consider a longer time horizon.

5.13 In our case study, we define the capital for lapse volatility risk on the basis of the impact on the total liability, as opposed to a shorter term. If we were to measure on a shorter term horizon, we would establish virtually no capital, as the products in this company have little or no cash values, and the impact of adverse lapses on other cash flows over a short horizon is negligible.

5.14 The table below illustrates that even on the basis of the full term of the liability cash flows, the lapse volatility risk is relatively immaterial compared to the other risks:

A.6 Solvency Provisions for Expense Risk

6.1 A detailed understanding of the company’s expense structure and expense drivers is a key element when determining the expense risk. In the calculation of the capital for expense risk we distinguish between acquisition and maintenance expense risk. Possible methodologies used to estimate the expense risk economic capital can range from simple to complex. However more
importantly whatever methodology is used the process focuses on understanding the underlying structure of company expenses.

6.2 A few of the key risks facing an insurer include:

- Misclassification of expenses between acquisition and maintenance, with inappropriate liabilities being established for in-force policies
- Future changes in the product offerings of the company, leading to different cost structures in the future than current
- Unstable volumes of new business and in-force
- Inflation is different than expected

6.3 One simple method to calculate solvency capital for expense risk would be to calculate as a multiple of Fixed Acquisition Expenses plus Maintenance expenses. For example, one could require the company to have sufficient capital on hand to pay for one year of additional expenses, which might represent the length of time required for a regulator to settle a problematic situation.

6.4 Alternately, one could require that maintenance expenses be explicitly provided for by inflating the best estimate unit costs by a factor that varies based on the stability and accuracy of the company’s expense studies. In this way, the total solvency provision would provide for the present value of best estimate maintenance expenses to mature the in-force policies, plus an additional provision that might range from , say 2.5% to 10% of this amount. Under this model, acquisition expenses would not be explicitly provided for as Pillar 1 capital, but could be covered under Pillar 2, in which a periodic review of the company’s expense study would be performed.

6.5 Additionally, inflation could be covered by putting an explicit margin on the inflation assumption and revaluing the liabilities.

A.7 Solvency Provisions for Market Risk

A.7.1 Mismatch Risk (ALM Risk)

A.7.1.1 Internal Models

7.1 The mismatch risk considers the risk that the best estimate cash flows arising from the assets supporting the liabilities, do not match the best estimate liability cash flows, which results in required reinvestment, disinvestments or borrowing required by the insurer to satisfy liquidity needs. Because the future reinvestment environment is uncertain, this can result in additional gains or losses to the insurer based on the market values of the assets at those future points in time. In other words, this risk is ultimately that the market price of the assets changes unfavorably at a time when those assets need to be liquidated.

7.2 To quantify this risk using internal models, we perform the following calculation, under two sets of stochastic reinvestment scenarios:

- First, we project the best estimate asset and liability cash flows arising from the portfolio under the stochastic reinvestment scenarios being tested. This results in net cash flows being available for reinvestment or disinvestment in each future period. These cash flows are dealt with according to an assumed reinvestment strategy, that is based on the insurers actual strategy. Future reinvestment rates are modelled based a double mean reverting process., where future yield curves are modelled based on a random walk, but where the mean rate is based on a probability distribution.
In each scenario, the insurer will be left with a certain amount of surplus or deficit at the end of the projection. We then solve for the amount of additional assets needed at the beginning of the projection, such that we end the projection with a zero balance.

The assets required under the base scenario are also determined. The base scenario assumes that future reinvestment rates are the best estimate, or average, of the rates projected under each of the stochastic scenarios.

7.3 Two sets of stochastic scenarios of future reinvestment rates are tested.

First, we generate future reinvestment rates from the current yield curve as of the current valuation date. A total solvency provision is determined as the difference between the assets required at TVaR_{99\%} and the best estimate assets;

The second tests are to generate future reinvestment rates from a shocked yield curve at the current valuation date. The shocked yield curve is derived from the current yield curve by applying the maximum shock that is likely to occur to the yield curve in a 1-year period with 99.5% confidence. A solvency provision is then determined as the difference between the assets required at a lower confidence level such as TVaR_{75\%} and the best estimate assets.

7.4 The final provision is based on the greater of the two calculations. The intention of this calculation is to ensure that the Company has at least enough money to establish liabilities at a lower confidence level, such as CTE (75), having survived an adverse yield shift as might occur in a 1-year period, or to provide for longer term mismatch.

7.5 In our case study, the first test produces a larger figure. The table below summarizes the capital requirements that we derive. As a matter of interest, the scenarios that produce the largest liabilities are the low interest scenarios.

A.7.1.2 Considerations for Standardized Approaches

7.6 A simpler standardized approach is one that would not require the company to perform asset-liability modelling. We would instead require the company to measure various statistics about the degree of mismatch, and develop factors based on that. In developing these factors and the corresponding exposure measures, it is important to be aware of the limitations of each simplified approach, and perhaps introduce additional rules that deal with those limitations.

7.7 For example, one possible standard factor approach might consist of applying factors to the assets supporting a block of business, where the factors vary based on the difference in Macaulay duration of the assets and liabilities. It is well understood, however, that duration measures do not reflect the degree of cash-flow mismatch very well. It is certainly possible for a portfolio to have grossly mismatched asset and liability cash-flows, but with virtually equivalent asset and liability durations. If such a duration-based capital requirement were implemented, it might also be appropriate to require a minimum amount of capital to deal with this shortcoming. Adjustments might also have to be developed for unusual situations with respect to the exposure base.

7.8 A simpler approach is to assume that all portfolios of like characteristics are duration mismatched to the same degree. A set of factors could then be developed that vary only with the characteristics of the liability portfolio, such as the length of guarantee periods remaining, the ability of policyholders to withdraw funds, etc.

A.7.2 Credit Risk

7.9 The case study also includes capital provisions for asset default risk. These provisions have been established using capital requirements from Basel II, which is a new accord being developed to provide more flexibility and risk sensitivity than exists in the original 1988 Basel Accord. The 1988 Basel Accord established credit risk as eight percent of risk weighted assets, where the risk weights are prescribed by type of asset. For example, all corporate bonds are given a 100% risk-weight in the 1988 Accord (regardless of credit rating), and OECD government bonds have a weighting of zero. Under Basel II, a bank will have a choice of three approaches for capital provisions:

- Standardized Approach: This is very similar to the original 1988 Basel Accord, except that the risk-weightings applied to each asset are based on a credit rating from an external rating agency.

- Foundation Internal Rating Based (IRB) Approach: Under this approach, a bank would develop its own risk weightings for each counterparty exposure, based on its own internal model. The risk weightings are achieved through a specified formula that takes into account the probability of default (from banks internal model), time to maturity and loss given default. The time to maturity is prescribed to 2.5 years, and the loss given default is 50% for all assets.

- Advanced Internal Rating Based (IRB) Approach: This approach is similar to the Foundation approach, except that the actual time to maturity of the assets is reflected, and the loss given default is also generated from the bank’s internal model.

7.10 The case study is specifically based on application of the Basel II “Advanced IRB” Approach. Our internal model is used to generate probabilities of default, time to maturity and loss given default, for each of the assets in the portfolio. Application of the Basel II formulae results in capital provisions for these assets. Although designed as a banking application, we see no reason to recommend a different approach for insurance company solvency assessments in general, and for this case study in particular.
7.11 In the table below, the capital provisions using the Basel II Advanced approach are summarized. For illustrative purposes, the impact of using alternate regulatory models (i.e., the Basel II “Standardized” and “Foundation” approaches, as well as the original 1988 Accord) and several internal models is also shown.

7.13 The Basel II (Advanced) model generates capital provisions of 2.7% of exposure at default (par value), based on the actual times to maturity of the assets in our portfolio, and based on our internal model estimates of probabilities of default. It is interesting to note that the Basel II (Standard) approach gives a slightly higher capitalization because of the use of prescribed risk weighting factors that vary only by credit rating. In the Basel II (Foundation) model, we generate significantly lower capital requirements than both the Standard and Advanced approaches, because we are allowed to reflect our own internal probabilities of default but are required to use an average time to maturity of 2.5 years. While this may be representative of a typical banking
book, most life insurance portfolios are of longer duration, which suggests that the Foundation approach may not be appropriate for life insurance asset portfolios. In the internal model results, we use three independent models. The first of our three internal models also generate capital requirements between 1.6% and 3.5% of exposure at default. The first model (the KMV model) attributes capital based on probabilities of default, loss given default, correlation between assets, and also the diversification of the portfolio. 9 The second and third models are described in the Institute of Actuaries of Australia paper by Martin Paino and Greg Martin, as being an adjusted Default model (DM) and an adjusted Mark to Market (MTM) model, shown as Model (2) and Model (3) respectively in the table above.

7.14 Capital requirements for asset default should only be based on those assets that support the liabilities and required capital of the company. Ideally, we would not establish provisions for assets that support the free surplus, for reasons explained in this Report. Ignoring asset defaults on free surplus assets would result in an iterative process to determine capital requirements. This is because the free surplus and the asset default capital requirements are inter-related. For simplicity, we have ignored this in the case study, and have simply shown asset default capital requirements for all assets in the company, regardless of whether the asset is considered free surplus.

7.15 The asset default requirements in the case study are considered “type A”, which means that they provide for asset defaults on existing assets only. Because of the long term nature of life insurance, insurers must also be concerned with “type B” asset default risks, that is, asset defaults on future assets purchased by the insurer with future positive cash flows. We have provided for this in the case study by discounting liability cash flows at a risk-free rate. The spread between the risk-free rate and the expected returns of specific assets, however, reflect both asset default and liquidity risks, and so, we may be overly conservative in the case study by assuming that the entire spread represents an asset default provision.

A.8 Effects of Reinsurance on Internal Model

A.8.1 Effects on Insurance Risk

8.1 Our case study until now has been based on the assumption that there is no reinsurance in place. Suppose now that the company wanted to reinsure the mortality risk for one of its product segments, ALC 1001. The reader will recall that this product is a term to 100 product with approximately 56,000 lives in it, and approximately $150 million of liabilities as measured on a best estimate basis at the risk-free rate.

8.2 We are interested in the effects of various reinsurance structures on the mortality risk, both as regards the product ALC 1001 on a stand-alone basis, but also as it affects the total provisions for mortality risk.

8.3 We consider several different types of reinsurance arrangements. For the purposes of this analysis, we differentiate the reinsurance arrangements into 2 categories:

- Reinsurance that guarantees the future mortality cost for a portion of the risks, with reinsurance premiums guaranteed at the Company’s expected mortality level for a period of time;

- Reinsurance that guarantees and lowers the future mortality cost for a portion of the risks. Reinsurance premiums in these cases are guaranteed at lower rates than the Company’s expected mortality levels.

---

</tr>
<tr>
<td>7. Quota Share</td>
<td>Reinsurer accepts 45% of all cashflows</td>
<td>45% of all cashflows</td>
<td>N/A</td>
</tr>
</tbody>
</table>

8.4 The results are shown in the table below. The following comments are noteworthy:

1. The reinsurance is designed to cede away 45% of the risk, approximately (except in one case). As we can see in the table, the level and trend risks are indeed ceded away by roughly that amount, but the specifics depend on the structure of the reinsurance. For example, when we lock in premiums of 70% of the expected table, which is the same as the Company expected mortality cost, then we do indeed cede away approximately 45% of the risk. When we lock in more favorable rates, however, we see that the level and trend risks actually increase relative to the 70% premiums (The liability itself decreases by $60 million because of the more favorable rates (not shown), but the capital relative to this figure increases). This is because we’ve changed our exposure to the risk. With these new terms, reinsurance becomes more expensive relative to the best estimate liabilities in favorable mortality improvement scenarios.
2. Obviously, if the goal is to control the volatility risk, then an excess retention structure is better. These structures reduce the volatility and catastrophe risk without materially impacting the level and trend risks. On this issue, though, it is important to note that many capital standardized systems do not differentiate between the types of reinsurance structures. In Canada, for example, the capital for volatility and catastrophe would be the same for all of these reinsurance structures, even though clearly, the form of the structure affects the risk.

3. On the 90% coinsurance arrangement, we’ve ceded away over 90% of the level risk, but only 80% of the trend risk. In addition, the exposure has actually changed direction. The company is now better off if mortality worsens, because the company is only exposed to 10% of the actual mortality losses in current periods, and stands to gain on a reduction of future reinsurance premiums on the 90% that is ceded. A standardized system would only be able to capture such a dynamic if the assumptions themselves were carefully mandated, and not through simple use of factors.

### A.8.2 Counter-party Risk

8.5 Under the various reinsurance arrangements discussed above, the company would be subject to additional credit risk in the form of counter-party risk. This could be quantified by applying factors to the amount exposed to risk of default by the counter-party, i.e., the reinsurer.

8.6 One approach that could be taken is to base the probability of default on the credit rating of the reinsurer. For example, if the reinsurer in our case study were rated “A”, we could assume probabilities of default consistent with any “A” rated asset as per Basel II. Using the Basel II (Foundation) factors, we would assign an annual probability of default of 0.7%.

8.7 The amount of risk exposed would reflect the amount of assets that the Company would lose should the reinsurer default. This would include any outstanding receivables from the reinsurer net of outstanding payables at a minimum, but may also include reserves ceded to the reinsurer which would have to be re-established on the balance sheet of the company. Reserves might be too conservative an estimate of the amount at risk, however, as the Company would potentially have the opportunity to obtain replacement coverage.
A.9 Conclusions

9.1 The case study highlights that one can conceptualize an advanced model for a life insurance company that in turn can be used to develop a standardized approach for those life risks that are well understood and for which there is ample historical data. One must exercise more care in developing a standardized approach for other life risks, to ensure that the impacts of policyholder behavior, complex options in the policies and the complex interactions between risks are reflected in an appropriate manner.
Appendix B  Non-Life (P&C) Insurance Case Study

B.1 Introduction

1.1 This non-life insurance company case study has been prepared by the WP to illustrate some of the concepts discussed in this report. The main purpose of the case study is to describe calculations that a company might undertake in order to determine total solvency provisions for various risks, and to highlight some of the issues in these calculations.

1.2 This non-life insurance company case study has been prepared by the WP to illustrate some of the concepts discussed in this report. The main purpose of the case study is to describe calculations that a company might undertake in order to determine total solvency provisions for various risks, and to highlight some of the issues in these calculations.

1.3 This case study begins by using a model of insurer aggregate losses to calculate the assets needed to support the insurer’s liabilities. The model produces the distribution of the total loss arising from post calculation date exposures and unpaid claims liabilities arising from past exposures. From this distribution, we set the required assets equal to the Tail Value-at-Risk, evaluated at the 99% level ($TVaR_{99\%}$).

1.4 These assets can come from two sources. The first source is from the policyholders, after the provision for the various reserves and expenses (including reinsurance expenses) are removed. The second source is the investors, through either a direct contribution to capital or from retained earnings from prior years of operation.

1.5 In this case study, the risk-based capital charge is defined as:

$$TVaR_{99\%} – \text{Expected Net Losses on Current Business} – \text{Net Loss Reserve}$$

1.6 The reserves are set at the expected value of future payments with no discounting for the time value of money. The size of the reserves to subtract from the assets deserves some discussion. The loss reserve could be set at the expected present value of future payments. If a more conservative estimate is desired, an insurer could remove the discount for the time value money, or even require a more conservative estimate. Ultimately, such a decision is left up to the insurance regulators.

1.7 This case study concentrates on underwriting risk and does not consider other sources of risk. A complete risk-based capital formula should also consider asset risk and well as the risk of premium deficiency, i.e. the risk that the market will not allow adequate premiums.

1.8 This case study illustrates two ways to calculate the insurance risk portion of the minimum capital requirement for a general insurance company. The first calculation will be a factor-driven formula where the parameters can be specified by either the regulator, or by the insurer – presumably with the regulator’s approval. The second calculation will be derived from a more detailed model of the insurer’s underwriting risk.

1.9 The working party proposes that the regulator prescribe a factor-based formula as a starting point for a risk-based capital analysis. Since it is a starting point, it should be subject to the operational constraints.
• Simplicity – The formula can be put on a spreadsheet. This may allow for some complexity in the formulas, as long as the objective of the formulas is clear.
• Input Availability – The inputs needed for the formula are either readily available, or can be reasonably estimated with the help of the appointed actuary.
• Conservative – When there is uncertainty in the values of the parameters, the parameters should be chosen to yield a conservative estimate of the required capital.

1.10 The working party proposes that, with the regulator’s approval, an insurer may substitute its own internal model for the factor based formula. The internal model can be a minor change to the factor-based formula, or a completely different model. The regulator may want to set standards for internal models. A set of standards is proposed elsewhere in this report.

1.11 The case study will cover two different insurance companies each with three different reinsurance strategies.

B.2 The Insurance Companies

2.1 We illustrate the risk-based capital calculations on the hypothetical ABC Insurance Company and the XYZ Insurance Companies. Table 1 gives premium and loss reserve statistics for these insurance companies. Here are some additional details about these companies.

- The lines of insurance covered by these insurers are standard personal and commercial lines that are typically written by an insurer in the USA. In addition, there are separately identified catastrophe coverages.
- The distribution of losses was generated with the collective risk model. This model describes the losses in terms of the underlying claim severity and claim count distributions.
- The claim severity distributions for each insurance company are identical. The claim count distribution for the ABC Insurance Company has a mean that is ten times the mean of the claim count distribution for the XYZ Insurance Company for each line of insurance. As a consequence, expected loss for ABC is ten times that of XYZ for each line of insurance.
- Three different reinsurance strategies are considered. The first strategy is no reinsurance. The second strategy covers 95% of the losses in excess of $50 million ($5 million) of catastrophe losses for ABC (XYZ), but provides no coverage for the other lines. The third strategy adds a $1 million limit on the non-catastrophe lines.

B.3 The Loss Model Underlying the Factor Based Formula

3.1 In this case study, we give an example of a factor-driven risk-based capital formula. This formula is sensitive to:

1. The volume of business in each line of business;
2. The overall volatility of each line of insurance;
3. The reinsurance provisions; and
4. The correlation, or dependency structure, between each line of business.

3.2 The formula requires the insurer to input expected losses (and expected future payments for loss reserves) by line of insurance. Other parameters (specified below) can be determined by either the regulators or the insurers.

3.3 The formula is derived from a model that can be visualized as a computer simulation of the losses for each line of insurance. Using the parameters of the model, it calculates the first two moments of the aggregate loss distribution and then estimates the Tail Value-at-Risk at a selected level 99%, \( (\text{TVaR}_{99\%}) \), by assuming that the aggregate loss distribution is lognormal.

3.4 What follows is a more technical description of the model.

3.5 Simulation Algorithm Underlying Factor-Based Formula

1. For each line of insurance \( i \), with uncertain claim payments, do the following:
   - Select a random number \( \chi_i \) from a gamma distribution with mean 1 and variance \( c \).
   - Select a random claim count \( K_i \) from a Poisson distribution with mean \( \chi_i \cdot \lambda_i \) where \( \lambda_i \) is the expected claim count for line of insurance \( i \).
   - For each \( i \) and for \( k = 1, \ldots, K_i \), select a random claim size, \( Z_{ik} \), from a lognormal distribution with mean \( \mu_i \) and standard deviation \( \sigma_i \).

2. Set \( X_i = \sum_{k=1}^{K_i} Z_{ik} = \text{Loss for line of insurance } i \).

3. Select a random number \( p_i \), from a uniform (0,1) distribution. For each line \( i \), select \( \beta_i \) to be the \( p_i \)th percentile of a distribution with \( E[\beta_i] = 1 \) and \( \text{Var}[\beta_i] = b_i \). This gives a multivariate distribution of the \( \beta_i \)'s in which each coefficient of correlation, \( \rho_{ij} \), is equal to 1.

4. Set \( X = \sum_i \beta_i \cdot X_i = \text{Loss for the insurer} \).

3.6 Here are the formulas used to calculate the first two moments of \( X \).

1. \( E[X_i] = \lambda_i \mu_i \)
2. \( E[X] = \sum_i E[X_i] \)
3. \( \text{Var}[K_i] = \lambda_i + c_i \lambda_i^2 \)
4. \( \text{Var}[X_i] = \lambda_i \sigma_i^2 + \mu_i^2 (\lambda_i + c_i \lambda_i^2) \)
5. \( \text{Var}[\beta_i X_i] = \text{Cov}[\beta_i X_i, \beta_j X_j] \)
   \[ = (1+b_i)\text{Var}[X_i] + E[X_i]^2 b_i = (1+b_i)(\lambda_i \sigma_i^2 + \mu_i^2 (\lambda_i + c_i \lambda_i^2)) + b_i \mu_i^2 \lambda_i^2 \]
6. For \( i \neq j \) \( \text{Cov}[\beta_i X_i, \beta_j X_j] = \lambda_i \mu_i \lambda_j \mu_j \rho_{ij} \sqrt{b_i b_j} \) (Note that we assume that \( \rho_{ij} = 1 \).)
7. \( \text{Var}[X] = \sum_i \sum_j \text{Cov}[\beta_i X_i, \beta_j X_j] \)
3.7 Given the mean and the variance of the insurer’s aggregate loss distribution one can calculate \( TVaR_\alpha(X) \) by the following steps. This description will make use of formulas for the lognormal distribution in Appendix A in the book, *Loss Models* by Klugman, Panjer and Willmot\(^\text{10}\) (KPW).

1. Calculate the parameters of the lognormal distribution that has the same mean and variance of the insurer’s aggregate loss distribution.

2. Calculate the Value-at-Risk at level \( \alpha \), \( VaR_\alpha(X) \), (i.e., the \( \alpha \)th percentile) of the lognormal distribution.

3. Calculate the limited expected value, \( E[X^{VaR_\alpha(X)}] \) for the lognormal distribution.

4. Then \( TVaR_\alpha(X) = VaR_\alpha(X) + \frac{E[X] - E[X^{VaR_\alpha(X)}]}{1-\alpha} \)

3.8 Using the Poisson distribution to model claim counts and the lognormal distribution to model claim severity are fairly standard assumptions in the actuarial theory of risk and we will not discuss these further. The role of the “\( b \)” and “\( c \)” parameters is not standard and thus it deserves some discussion.

3.9 Introductory treatments of insurance mathematics often make the assumption that there are \( n \) identical insurance policies each with independent and identically distributed loss random variables \( X_i \). Let \( X \) be the sum of all the \( X_i \)’s. Then the variance of the loss ratio, \( X/E[X] \) is given by \( \text{Var}[X]/(nE[X]) \). This model implies that as \( n \) increases, the variance of the loss ratio decreases with the result that a very large insurance company can write insurance with minimal risk.

3.10 Let us now apply the same idea to a line of insurance defined by our model above.

\[
\text{Var} \left[ \frac{\beta_i X_i}{E[\beta_i X_i]} \right] = (1+b_i) \left( \frac{\mu_i^2 + \sigma_i^2}{\lambda_i} + c_i \right) + b_i
\]

3.11 As \( \lambda_i \) increases, the variance of the loss ratio decreases, but it never decreases below \( b_i + c_i + b_i c_i \). This means that, unlike the introductory result, an insurer will always be exposed to risk regardless of how many policies it writes in line \( i \). This model better resembles the real insurance environment because a changing economic environment always makes the outcome of writing insurance uncertain.

3.12 Meyers, Klinker and Lalonde\(^\text{11}\) (MKL) show how to estimate the \( b \) and \( c \) parameters from industry data. Making the assumption that the \( b \) and \( c \) parameters are the same for all insurers, they show how to estimate there parameters from the reported loss ratios of several insurers.

3.13 An experienced observer of insurer loss ratios by line of business should be able to develop some intuition about the magnitude of the \( b \) and \( c \) parameters. Note that loss ratios for large insurers are less volatile than smaller insurers. Note that the \( c \) parameters affect correlation between individual insurance policies within a line of business, while the \( b \) parameters affect correlations between lines of business. One can also form some intuition about the kind of events that drive insurer loss ratios across lines of business, such as inflation, and the degree to which these events are predictable.

Copyright © 2004 International Actuarial Association
3.14 Simple analyses of industry accident year loss ratios by line of business can provide a rough quantification of $b_i + c_i + b_i c_i$. As an example, let’s suppose that one estimates that the standard deviation of the loss ratio (actual loss divided by expected loss) for a line of business can be no smaller than 20% regardless of the size of the insurer. This would tell us that $b_i + c_i + b_i c_i$ is equal to $0.2^2 = 0.04$. Suppose further that we estimate the standard deviation of inflationary effects to be 5%. This means that $b_i = 0.05^2 = 0.0025$. Then $0.04 = 0.05^2 + c_i + 0.05^2 c_i$ which implies that $c_i = 0.0374$.

3.15 The intuitive ideas expressed in the above two paragraphs are formalized in the estimation procedure provided in MKL.

B.4 Calculating the Risk-Based Capital with a Factor Based Formula

4.1 To use the above model to calculate the risk-based capital the regulators, in consultation with the insurers, must determine the following parameters, before the application of the reinsurance, of the loss model for each line of insurance for both current business and unsettled claims for past business.

- The expected value of the lognormal claim severity distribution
- The coefficient of variation, $CV_i$, of the lognormal claim severity distribution
- The $b_i$ and $c_i$ parameters

4.2 The parameters used in this case study are given in Table 2 below.

4.3 Using formulas in Appendix A of KPW, the insurer then calculates the parameters $\mu_i$ and $\sigma_i$ after the application of reinsurance. The $\mu_i$’s and the $\sigma_i$’s for no reinsurance, and for reinsurance covering the excess over $1$ million per claim are given in Table 3.

4.4 The next step is for the insurer to provide estimates of the expected claim counts, $\lambda_i$, for each line of insurance. These estimates are derived by dividing the expected claim severity, $\mu_i$, into the insurer’s estimate of expected losses by line of insurance. These insurer estimates are based on its volume of business in each line. Table 4 contains the $\lambda_i$’s used in this case study. These $\lambda_i$’s were determined by dividing the $\mu_i$’s in Table 3 into the insurer estimates of its expected losses by line when there is no reinsurance.

4.5 Tables 2, 3 and 4 above give all the information necessary to calculate the mean and variance (or standard deviation) of the aggregate loss distributions for each insurer and reinsurance strategy using the formulas provided in the previous section. The results of these calculations are given in Table 5.
Table 5

<td>186,362,345</td>
</tr>
</tbody>
</table>

4.6  It is worth noting that while the expected losses for ABC are exactly ten times the corresponding expected losses for XYZ, the standard deviations for ABC are less than ten times the corresponding standard deviations for XYZ.

4.7  Now that we have the means and variances of the aggregate loss distributions we turn to calculating the risk based capital. Following the formulas outlined in the previous section we calculate the $TVaR_{99\%}$ for each insurer and reinsurance strategy.

4.8  As noted above, the $TVaR_{99\%}$ was calculated by approximating the aggregate loss distributions with a lognormal distribution with the same first two moments. The working party did not feel that this was appropriate when the insurer was exposed to catastrophic risk. Thus the formula determines the final risk-based capital for the underwriting risk by adding a catastrophe probable maximum loss to the $TVaR_{99\%}$. In this case study we used the 99th percentile of a catastrophe loss distribution generated by the catastrophe model maintained by Applied Insurance Research. Thus the formula for the risk-based capital is given by:

$$TVaR_{99\%} - \frac{\text{Expected Net Loss}}{\text{On Current Business}} - \frac{\text{Net Loss Reserve}}{\text{All Lines}} + \text{Catastrophe PML}$$

4.9  The final risk-based capital calculations for the various reinsurance strategies are included in Table 6.

4.10  While this factor based formula does involve a number of equations, it can be implemented on a fairly compact spreadsheet. The necessary mathematical manipulations are doable by a recently trained actuary.
B.5 Calculating the Risk-Based Capital with an Internal Risk Management Model

5.1 It should be clear that there are several alternatives to the model underlying the factor based risk-based capital formula. The working party believes that a model underlying a prescribed risk-based capital should be deliberately conservative. The working party proposal allows the insurer to use its own model for risk-based capital calculations, subject to standards for risk-based capital formulas. This section gives an example of such a model.

5.2 The model described here is applied to the ABC and XYZ insurance companies. It differs from the model used in the factor-based formula in the following respects.

- The choices of the claim severity distributions were not conservative. It uses claim severity distributions that were derived from its own analysis of claim severity.
- The structure of the model is richer. Random multipliers applied to the claim count distributions across lines allow for a relaxation of the conservative assumption that $\rho_{ij} = 1$ for all lines of business $i$ and $j$.
- The model calculates the aggregate loss distribution directly, rather than approximate the aggregate loss distribution with the first two moments.
- Determining the needed assets for the insurer by adding the catastrophe probable maximum loss to the $TVaR_{99\%}$ is in essence, adding “worst case scenarios.” The catastrophe model was incorporated directly into the internal risk-management model.

5.3 Additional details on the construction of this model are given by MKL. Table 7 gives the risk-based capital charge derived from the internal risk management model for the ABC and XYZ Insurance Companies for the various reinsurance strategies.

B.6 Provisions for Adverse Deviations in Reserves

6.1 The working party also considered methods for including a provision for adverse deviation (PAD) in the reserves. In this section we give an example of how this might work with the factor based formula.

6.2 Rather than book the reserves for losses at their expected value, this example first calculates the PAD as the tail value-at-risk at the 75% level minus the expected loss for the reserve in each line of insurance. The PAD calculation is also done for the expected loss in current business.
6.3 Next the PAD is calculated for the insurer in total. Because of diversification, this PAD is less than the sum of the PADS for each line of business. The each line of business PAD is adjusted proportionally so that the line of business PADS sum to the overall PAD.

6.4 Note that the total assets for the insurer remain the same, and the expected losses remain the same. The PAD’s simply shift a portion of the capital over to the insurer’s liabilities.

6.5 The results of these calculations for the ABC and XYZ Insurance Companies are included in Table 8.

Appendix C  Health Insurance Case Study

C.1  Introduction

1.1  This health insurance company case study has been prepared by the WP to illustrate some of the concepts discussed in this report. The main purpose of the case study is to describe calculations that a company might undertake in order to determine total solvency provisions for various risks, and to highlight some of the issues in these calculations.

1.2  This case study should be regarded as a general example in which typical health insurance issues are discussed, with a focus on medical insurance. As there are major differences between coverages, policy conditions and legislation of health insurance arrangements in different countries, it is not possible to cover all existing arrangements here.

1.3  This Appendix contains methodology for modeling risks in medical insurance and related products. A categorization of the risks is made into volatility, uncertainty and extreme event elements, as outlined in the main report.

1.4  In the next section some special features of medical insurance are discussed. The third section comments on the model structure while the fourth section discusses the separate risk categories in more detail, illustrated by case studies. In the fifth section a separate case study for medical inflation is shown. Finally the sixth section discusses methodologies for standardized approaches and aggregation.

C.2  Special Features of Medical Insurance

2.1  In this section some of the special features of medical insurance are discussed. Due to these special features the models for Life and P&C insurance risks may not always be sufficiently equipped to deal with medical insurance.

C.2.1  Medical Inflation

2.2  Medical expenses generally show a tendency to increase more than general inflation. There are several explanations for this phenomenon.

2.3  Developments in the field of medical technology can lead to increases of the overall expense level in health care. For example, some technological developments have lowered the expenses involved in the treatment of specific illnesses and have provided better outcomes for the persons with those illnesses. Some new technologies have dramatically improved the detection rate of certain illnesses, which then leads to rapid increases in the overall costs of treating those illnesses and usually much improved success rates. Other new technologies have greatly increased the cost of treatment of certain illnesses usually with significantly better outcomes (often the patient living considerably much longer). Finally there are a number of new technologies that have significantly reduced the risk of poor outcomes from certain treatments thus enabling these treatments to be provided to a much wider group of patients.

2.4  In the future, new detection technologies, while relatively cheap, are likely to be very widely demanded. Also, the further individualization and increased sophistication of medical interventions is unlikely to reduce the overall rate of growth in the expense levels of health care. The resulting longer life expectancies that are obtained from new medical technologies will also enable some people who benefit from these technologies to consume even more medical resources over their lifetime.
2.5 Improved information gathering, recording and reporting leads and will lead to efficiency gains, which enable many more conditions to be detected and/or treated external to the labor intensive hospital setting. But many of these conditions would not have been detected and/or treated prior to these technology changes so the efficiency gains eventually show up as long-term improvements in population health status and, to some extent, longevity - outcomes, which are hard to measure or relate back to the technologies in the short term.

2.6 As a result of efficiency gains in other sectors of the economy the cost of labor increases in all sectors including the health sector. As there is little efficiency gain in the hospital sector which can reduce the number of staff required the overall expense level of this sector of health care can be expected to become relatively more expensive. The hospital sector in particular is relatively labor-intensive so there are generally less efficiency gains which can be realized through automation than there are in other sectors of the economy. The skill sets of hospital labor are also being constantly upgraded, which is putting further pressure on labor costs.

C.2.2 Political Risk

2.7 It is common for democratically elected Governments to make promises in respect of the supply of health care services. In endeavoring to reduce their health expenditure these Governments will then often try to reduce the price of health care by controlling the supply of health care services through various rationing techniques including through the control of prices health care professionals can obtain for their services. These constraints do tend to reduce expenditure in the short to medium term but in the longer term the eventual constraints on supply of quality services create their own political risks.

2.8 A further method of reducing Government health expenditure is to regulate both the market for private health insurance and the extent of the services covered by private health insurance. So Governments often dictate policy conditions and premium rates of medical insurance so that it may not be possible to fully adjust rates and conditions to the level commercially desired.

2.9 In the field of disability insurance, incidence rates and periods of disablement may also be influenced by Government. Sometimes incidence and periods of disablement are influenced by Government mandated benefit levels or Government mandated underwriting requirements.

C.3 Modeling Structure

3.1 The modeling structure includes a ‘best estimate’ and various types of risk. The best estimate is the expected claims liability that will result for the insurer. Due to various types of risks, the best estimate will in reality almost never materialise, but a higher or lower claims liability will occur.

The best estimate is discussed in the first subsection, risk types are discussed in the second subsection.

C.3.1 Best Estimate

3.2 The best estimate is the expected liability under the in-force contract. We distinguish between the best estimate in the first period and in the periods thereafter. The term is expressed as a “period” because medical insurance modeling is in some cases done annually, and in others quarterly or monthly.
3.3 The best estimate (BE) in the first period is determined as:

$$BE \text{ first period} = n \cdot d \cdot l$$

with

- \(n\): average number of insured in the in force portfolio during the period;
- \(d\): discount factor applied to reflect that claims occur on average in the middle of the period. In projections over short periods or in low interest rate environments \(d\) is usually excluded from the equation.
- \(l\): expected incurred claims liability per insured.

3.4 In this formula the impact of lapses is ignored, which leads to a more conservative estimate of the liability. In the longer term, lapses may result in an antiselection effect against the insurer (i.e. higher lapse rate for insureds who are less likely to claim). However the effect of antiselection is limited in the short term, especially when premiums have been received in advance for the entire contract period.

3.5 The approach described above can be used for products where premiums are periodically adjustable so that a best estimate projection is only needed for the first period. In the case of products with multi-period guarantees, or where there are conditions that restrict the insurer’s ability to increase premium rates to reflect increasing claim costs, a more sophisticated model approach is required. Such an approach takes into account the development of the expected incurred claims amount and the impact of lapses over longer periods.

C.3.2 Risk Types

3.6 Three types of risks are distinguished which will cause the actual liability to deviate from the best estimate.

3.7 Volatility Risk: the risk that the actual frequency and severity of claims differs from the best estimate in the particular period under consideration, but the expected liability for the average insured in the whole population is correctly estimated. When projections are performed for monthly or quarterly periods then it is also important to consider the seasonal effects on the volatility of claim rates.

3.8 Uncertainty Risk: the risk that the expected liability per insured is incorrectly estimated at present or it is correctly estimated at present but changes over time. Usually for multi-period models it is important to include at least the first order changes over time. These will be related to the change in the demographics of the insured population (for example the change in the average hospital utilization rates at older ages is greater than at younger ages) and the expected medical inflation rate for that insured population (this also tends to be higher for middle aged and older populations than younger persons). For some types of contracts, there can also be a moral hazard risk: the risk of individual insured persons deliberately selecting against the insurer. This can particularly happen in cafeteria arrangements or in any insurance arrangement when a number of choices are available to insured individuals.

3.9 Extreme event/Calamity risk: the risk of large one-off accumulation of claims outside the normal experience pattern.
C.4 Modeling Techniques

4.1 In this section the modeling of volatility, short term uncertainty and extreme event risk is discussed. A separate, more extensive case study for long term uncertainty caused by medical inflation is contained in section 5. For the short term risk model, the time period chosen is one year.

C.4.1 Volatility

4.2 The volatility risk is determined only for the first period of projection\(^{12}\). To determine volatility risk, the parameters driving frequency and severity of claims are assumed to be fixed and given. The remaining risk is the risk that the claims volume is different from its expected level due to randomly occurring deviations.

4.3 The volatility risk can be modeled with a probability distribution of the frequency and severity of the individual claims.

4.4 We define:

\[ N : \text{the number of claims}; \]
\[ X_i : \text{the claim size of the } i\text{-th claim, with } i = 1, 2, \ldots, N; \]
\[ S = \Sigma X_i , \text{the total claims volume}. \]

4.5 Furthermore we assume that:

The incidences of claims are mutually independent (i.e., there is no single cause leading to claims by different insureds).

The claim severities \(X_i\) are also independent and all have the same probability distribution.

4.6 Although these assumptions do not completely reflect reality, they work sufficiently well for a portfolio of reasonable size. Dependence between insureds caused by overall circumstances affecting the whole population is not reflected in the volatility risk. For example, if the costs of surgery increase as a result of new technologies invented, this will simultaneously lead to a higher claim severity for all insureds. However, this type of dependence will be captured in the uncertainty risk. Hence for the volatility risk calculation it is assumed that given the general cost level of surgery, the costs arising from individual claims are independent of each other.

4.7 An exception occurs when several people are involved in the same accident. In this case the incidences of their individual claims are not independent of each other. However, considering that accidents normally only involve a limited number of people, for a portfolio of several hundred insureds or more the impact of this type of dependency is very small. For accidents which can affect a large number of people, for example epidemics, industrial accidents or terrorist attacks, a separate ‘calamity’ risk charge needs to be added.

4.8 We are now interested in fitting a probability distribution for the total loss \(S\). This is done as follows. Firstly, expectation, variance and skewness of \(S\) are estimated. Then the normal power or translated gamma distribution is fitted to the estimated moments. As a result the expectation, variance and skewness of the estimated probability distribution of \(S\) are equal to the estimated moments. Both distributions can be used and generally will give outcomes in the same range. Also, when the number of independent insureds is large, the normal distribution will also give a good approximation due to the Central limit Theorem. For very low values of the skewness, the translated gamma distribution can cause computational difficulties.

---

\(^{12}\) See the section on ‘Time Horizon’ in the main report.
4.9 For the expectation, variance and skewness of \( S \), we have:

\[
E[S] = E[N]E[X_i] \quad (1)
\]

\[
\text{Var}[S] = E[N]E[X_i^2] \quad (2)
\]

\[
\gamma[S] = E[N]E[X_i^3]/\text{Var}[S]^{3/2} \quad (3)
\]

\( E[S] \) is the best estimate of the liabilities. As can be seen from the formulae above, the estimates of expected value, variance and skewness of \( S \) are found by estimating \( E[N] \), \( E[X_i] \), \( E[X_i^2] \) and \( E[X_i^3] \). This can be done in the following way: \( E[N] \), the expected number of claims is estimated as:

\[
E[N] = \text{number of insureds} \times \text{observed average claims frequency} \quad (4)
\]

\( E[X_i] \) is estimated as the average of the observed claim amounts, with a possible adjustment if claims in the next year are expected to be higher on average than in previous years. Similarly, \( E[X_i^2] \) is estimated as the average quadratic claim amount, and \( E[X_i^3] \) as the average third power of the observed claim amounts.

4.10 By using the average observed claims frequency for the portfolio as a whole we ignore the heterogeneity that is most likely present in the portfolio. For example, claim frequency increases with age of the insured. It can be proven that by ignoring heterogeneity a stop-loss safe estimation of the aggregate loss distribution is obtained, meaning the estimate contains some conservatism especially in the right tail of the distribution (see ‘Stochastic ordering’ by Kaas, Goovaerts et al).

C.4.2 Case Study Volatility

4.11 In this case study it is shown how a distribution function for the volatility risk of an arbitrary portfolio was estimated. The portfolio consists of 130,000 policyholders with an average claim frequency of 5% per year. The mean annual claim size is $4,125, which is simply the observed average in the latest year, with a possible loading for claims inflation/indexation. The input data used for the calculation are shown in table 1.

4.12 Table 1: portfolio and claims information

<table>
<thead>
<tr>
<th>Number of policies:</th>
<th>130,000</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average claim frequency per insured</td>
<td>5%</td>
</tr>
<tr>

</thead>
<tbody>
<tr>
<td>Variance</td>
<td>455,482,101,858</td>
</tr>
<tr>
<td>Skewness</td>
<td>0.20</td>
</tr>
</tbody>
</table>
With the estimated moments of $S$ given as input we will now fit three types of probability distribution: the translated gamma, the normal power and the normal distribution. This gives the following results:

Table 3: 99% upper limit of aggregate losses $S$ with respect to volatility risk

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Limit</th>

<td>28,381,385</td>
</tr>
<tr>
<td>Normal power distribution</td>
<td>28,478,771</td>
</tr>
</tbody>
</table>

The 99% point of the distribution function of the total liabilities is given below, meaning the total liability will be equal to or lower than the amount shown with a probability of 99%. As can be seen, the three approaches produce very similar results due the large number of (assumed) independent risks.

Uncertainty

Uncertainty risk can be split into the uncertainty risk in the first coming period and all periods thereafter. This split is useful to make as the short term uncertainty is of a different nature and more commonly present than the long term uncertainty in medical insurance products. The nature of the product and the possibility to adjust premium rates determine whether uncertainty risk beyond the first year needs to be considered. If rates can be adjusted periodically, this obviously reduces the long term uncertainty risk. But in many markets there is also the political factor that governs the extent to which premium rates can be adjusted. Usually the more politicized the rate setting process the greater the risk to the insurer of not being able to adjust premium rates to fully compensate for past errors in the estimation of future liabilities. In the next subsection, modeling approaches for the first year/short term uncertainty risk are discussed. The long term uncertainty risk for medical insurance is constituted by medical inflation risk and this is discussed in section 5.

Short Term Uncertainty Risk

The short term uncertainty risk in medical insurance can be treated in the same way as is done for P&C products, as described in the P&C case study. Using an approach that is based on loss ratios, the earned premium component of the loss ratio should be determined as the earned premium which is allocated to the calendar year under consideration. This earned premium can significantly differ from the written premium received minus expense allowances in the case that there is an ageing reserve. An ageing reserve allows the written premium to stay level over time or increase less while utilization increases due to the ageing of the insured population. In the presence of an ageing reserve the earned premium equals the written premium minus expenses allowances minus (plus) any addition (subtraction) from the ageing reserve.

The framework outlined in the P&C case study can be applied to medical insurance as follows:

There is a single line ‘medical insurance’ for which parameters $b_i$, $c_i$, $\lambda_i$, $\mu_i$ and $\sigma_i$ need to be estimated. As we are looking at a single line only, the index $i$ can be omitted so we will use $b$, $c$, $\lambda$, $\mu$ and $\sigma$ instead.

$\lambda$: expected claim count (number of in-force policies * expected claim frequency);
$\mu$, $\sigma$: parameters of the individual claim severity distribution.
$b, c$: parameters reflecting systemic risk in claims frequency and severity.
4.21 Following the approach outlined in the P&C case study, \( b \) and \( c \) can be estimated as follows:
The variance of the annual loss ratio of an imaginary, infinitely large portfolio equals:
\[
\text{Var(loss ratio)} = (b + c + bc) \cdot \text{E}[\text{loss ratio}]^2
\]  \hspace{1cm} (5)

4.22 As an approximation for the loss ratio of an infinitely large portfolio, one can use the industry-wide loss ratio for medical insurance. If for example, the expected loss ratio equals 60% and the standard deviation of the industry-wide loss ratio equals 20% then we have:
\[
\text{Var(loss ratio)} = (b + c + bc) \cdot \text{E}[\text{loss ratio}]^2 \quad \text{hence}
\]
\[
0.2^2 = (b + c + bc) \cdot 0.6^2 \]  \hspace{1cm} (6)

4.23 Also, \( b \) is the sole parameter indicating the variability of inflationary effects. As \( b \) is defined as the variance of a random variable \( \beta \) (as mentioned in the P&C case study) with expectation 1, we have:
\[
1 + \text{Medical Inflation}[t+1] = \beta \cdot (1 + \text{average medical inflation}).
\]
Therefore,
\[
\text{Variance (1+ Medical inflation}[t+1]) =
\]
\[
\text{Var}[\beta] \cdot (1+\text{average medical inflation})^2.
\]

Also,
\[
\text{Variance (1+ Medical inflation}[t+1]) = \text{Variance (Annual Medical Inflation})
\]
and \( \quad b = \text{Var}[\beta]. \)

It follows that:
\[
b = \text{Variance (Annual Medical Inflation}/(1+\text{average medical inflation})^2. \]  \hspace{1cm} (7)

4.24 From equations (6) and (7) we can now derive the values of \( b \) and \( c \). The P&C case study outlines the approach to determine the capital requirement based on the \( b \) and \( c \) parameters, as part of a standardized or advanced approach, and as a stand-alone line of business or as part of a P&C company.

4.25 We can also find the capital for the uncertainty risk alone by assuming independence of the volatility and the uncertainty component, as follows:
\[
\text{(Capital uncertainty)}^2 =
\]
\[
\text{(Capital uncertainty and volatility combined)}^2 - \text{(Capital for volatility)}^2.
\]

4.26 As in many jurisdictions medical insurance is underwritten by Life insurance companies rather than P&C companies, incorporation into a capital requirement for a Life company also needs to be considered. This will be addressed further in section 6.
C.4.5 Extreme Event Risk

4.27 The determination of the effect of an extreme event/calamity on a health insurance product will depend largely on the type of product, the type of calamity and the country that it is written in. A calamity, involving a large number of persons becoming ill or disabled for some period of time could have a major effect on a disability income product but very little effect on a hospital insurance product, written by the same insurer on the same group of lives.

4.28 Not all calamities require extensive hospitalisations of large numbers of people. Even if large numbers of people did require lengthy hospitalisation as a result of a calamity it is unlikely that the capacity of the local hospital system would cope. Often Governments will quickly react to calamities by providing additional facilities and support perhaps using defence force medical facilities or decommissioned hospitals. In these circumstances the cost is usually born by the taxpayer. Also in a state organised health insurance system if Government support was not forthcoming in the event of a calamity then all insurers or a group of insurers operating in the geographic area of the calamity would be likely to have financial difficulties together and the Government would not wish to see the market fail due to the eventual effect on Government outlays so capital adequacy rules would tend to be relaxed and/or regulatory measures introduced to ensure the rest of the industry assisted as necessary.

4.29 Reinsurance also can play a part in reducing the financial effect of a calamity. The extent of reinsurance support on an insurance product will also depend on the product and the country the product is written in. For products written in countries where there is little political inference generally insurers will have obtained catastrophe reinsurance to cover the effects of calamities. In some countries where there are taxation incentives to individuals or employees to be covered by medical and hospital expense insurance the Government may not even permit insurers to reinsure risk out of the local industry because of the taxation implications. In these environments there are often internal reinsurance arrangements or legislation compelling financially sound insurers to “prop-up” those that are not so sound financially.

4.30 As normally no or only very scarce data are available to calibrate extreme event risk, a pragmatic approach needs to be taken to determine a capital requirement. One can argue that the same causes that underlie the extreme event risk for mortality also apply to accident and medical insurance claims. Circumstances that cause increased mortality can cause increased medical and disability claims to the same extent. Hence, in line with the mortality approach, the combined capital for extreme event and the volatility and first year uncertainty risk can be determined by assuming claim frequency will double under these extreme circumstances while claim severity remains unchanged.

C.5 Case Study Medical Inflation

5.1 In this section a case study for the risk of long term medical inflation is discussed. The case study contains the following elements:

5.1 Medical inflation
5.2 Portfolio composition
5.3 Expected individual claim size by age/age cohort
5.4 Rating structure
5.5 Simulation
5.6 Results
C.5.1 Medical Inflation

5.2 On the basis of historical data, future medical inflation can be modeled using statistical and econometric modeling techniques.

5.3 The model applied in this case study is an autoregressive time series of the second order:

$$\text{INF}(t) = c_0 + c_1 \text{INF}(t-1) + c_2 \text{INF}(t-2) + \text{random error}(t)$$

with:

- $\text{INF}(t)$: medical inflation in year $t$;
- $c_0$, $c_1$, $c_2$: model parameters.

$\text{random error}(t)$: random, unexplained annual change of medical inflation rate.

5.4 The second order structure of the model implies there is a direct dependence between the inflation in a certain year and that in the two preceding years. As a result we have:

- Autocorrelation between successive observations: if the medical inflation is above (below) average in a certain year, it is likely to be above (below) average as well in the next year;
- Cyclicality: the second order of the model allows the possibility that there is a cyclical pattern in the observed inflation rates: possibly periods of several years with inflation rates above average are succeeded by several years with inflation rates below average.

5.5 It should be noted that it is assumed in this model that medical inflation is equal for all ages. When medical inflation is higher for higher ages than it is for lower ages, the inflation for a portfolio in run-off, with an increasing average age, will be higher than the overall medical inflation for the entire population.

C.5.2 Rating Structure

5.6 The current rating structure and the possibility to change rates in accordance with experience should be taken into account. Rate adjustments may be limited due to government restrictions or market movements. The model allows for rate adjustments equal to the minimum of:

- The annual medical inflation rate for the insured population as a whole;
- A maximum allowed annual rate increase.

5.7 These restrictions are given purely by way of example however different types of premium restrictions may be in force in various jurisdictions.

C.5.3 Portfolio Profile

5.8 The age distribution of the portfolio is given at the beginning of the projection period. No future new business is included in the current model setup. However for as far as the rating structure for new business is the same as for existing business, the model can easily be extended to allow for this. If a different rating structure is introduced for new business, one would have to allow for this by building a second model with the new rating characteristics. Expected lapse rates are assumed to be age dependent, decreasing with the age of the insured.

C.5.4 Claim Size by Age/Age Cohort

5.9 In the case study, the annual medical expenses increase exponentially with age, by way of an example. The values used can be replaced by any age-dependent estimate of the annual liability per insured, to represent expected medical expenses by age (group) in the present year. The effects of medical inflation are not yet taken into account in this stage of the calculation.
C.5.5 Running the Model Simulation

5.10 On the basis of the input described above model simulations are performed with which future medical inflation rates are simulated. Annual premium adjustments follow as a function of the inflation rates.

5.11 Volatility in lapses or incidences of claims of individual policyholders are not modeled by way of stochastic simulation. As the model projects over a very long period, e.g. 30 years or more, the effect of randomness of individual incidences of lapses and/or claims on policyholder level will be negligible. The uncertainty in the level of medical expenses in future years is a far more influential factor in determining the total liability.

5.12 Randomness in individual claim incidences is included in the volatility risk model (see section 4), but only in the first period.

C.5.6 Results

5.13 The simulation produces output in the following form:

5.14 A set of premium and claims cash flows in every future year that is included in the model for every run of the simulation.

5.15 A present value of claims and premiums for every scenario, based on a fixed discount rate or yield curve.

5.16 An estimate for the probability distribution of the present value of claims, the present value of premiums and the present value of claims minus premiums.

5.17 The present values of claims, premiums and their differences are expressed as a multiple of the risk premium for the portfolio as a whole at the inception date. The estimated probability distributions are shown graphically below.

Density of Net Liability by Age Cohort

5.18 In the graph, the density functions of the distribution of liabilities are shown for three different ages: 30, 40 and 50. The values are expressed as a multiple of the risk premium for the individual at the inception date of the projection. For example for the 40-year old insured the expected present value of the net liability (claims minus premiums) is approximately equal to 11 times the
annual risk premium for the insured at the inception date. A capital requirement can be determined as a percentile or TVaR (e.g. 99% or 99.5%) of the distribution. The medical inflation risk affects all policyholders simultaneously therefore there is no diversification between policyholders. As a result, a capital requirement, i.e. VaR/TVaR value, for a portfolio can be determined as the sum of the capital requirements for each individual policyholder or portfolio cohort.

C.6 Standardized Approach and Aggregation

6.1 In this section, a possible standardized approach for long-term medical inflation is discussed, as well as linking the different components discussed into an overall capital requirement.

C.6.1 Standardized Approach for Long Term Medical Inflation

6.2 Although it is very difficult to determine a universally valid standardized approach for medical inflation, one could proceed as follows. Starting from the recommendations in chapter 7 of the main report, three factors are distinguished in establishing a capital requirement under a standardized approach.

1. $\mu$: company specific expected losses;
2. $k$: specific to the line of business, prescribed by the regulator;
3. $v$: company specific factor.

1. As an exposure measure $\mu$, the total risk premium for the portfolio in any given year can be used.

2. The second factor $k$ can be determined by the regulator, as the ratio of the present value of future claims liabilities in a worst case, over the current total risk premium of the portfolio. The simulation model as described in the previous sections can be used to determine this factor based on a number of general portfolio characteristics such as the average (and possibly spread of ) remaining term of policies until expiration. Note that this factor only reflects the future claims liability, and not the premiums still to be received. This distinction is made because medical inflation is a phenomenon which affects all companies, while the possibilities of premium adjustments may vary by company.

3. The third factor $v$ is a company specific factor reflecting the rating of a particular company. This factor should reflect the adequacy of current rates as well as the possibility of adjusting rates in case of unexpectedly high future medical inflation. In the most extreme situations, $v$ will be 100% if no premiums can be charged at all in future years or 0 if future risk premiums can be charged to fully cover the worst case claims liability at all times.

6.3 If premiums can be adjusted without limitation but are currently inadequate, some additional capital will be required for the period that premiums will be inadequate, as the management of a company may decide not to raise premiums directly.

6.4 Where rate increases are subject to approval by a government body at the time they are submitted and this is based on judgement and political factors rather than a rigorous numerical rule, it is almost impossible to derive a factor reflecting this practice.

C.6.2 Aggregation of Capital Requirements for the Various Risk Components

6.5 In this case study, capital requirements have been determined for:

1. Short term volatility and uncertainty risk combined;
2. Short term extreme event (calamity) risk;
3. Long term medical inflation risk.

6.6 In order to derive an overall capital requirement for all of these risks combined, the following observations are made:

6.7 Short term volatility/uncertainty and extreme event risk can be regarded as more or less independent of each other. Extreme event risk, such as the outbreak of epidemics, is caused by unexpected one-off events which are generally unrelated to other developments leading to increased claims experience within the course of one year.

6.8 In the main report it is recommended that a capital requirement be determined as the maximum of two measures, one related to the first year, and one to all future years. Applying this recommendation to the health case study, the minimum overall capital requirement is found by taking the maximum of:

1. The capital required for category 1 and 2 combined at a very high confidence level;
2. The capital required for category 3 at a fairly high confidence level.

6.9 Capital requirements for category 1 have been determined using the approach for the P&C case study. However, as in many jurisdictions health insurance is underwritten by Life companies, consideration also needs to be given to correlations with other risks that life insurers are facing.

6.10 In section 7.2. of the main report, it is described how capital requirements for separate components of risks can be combined into a single overall capital requirement. This requires the determination of correlations between different types of risk. Although these correlations can best be chosen individually for each country or jurisdiction, it can be stated in general that:

6.11 Medical inflation tends to be generally higher than general inflation. The aggregate rate might be reasonably constant over time but it will vary between in-hospital and out-of-hospital services and also vary substantially between various types of out-of-hospital services (for example medical, pharmaceutical, dental and optical).

6.12 Medical inflation tends to be correlated with economic prosperity, as medical inflation is driven by technological development. Hence the extraordinary growth in the overall cost of pharmaceuticals and surgical implants.

6.13 As a result, medical inflation is most likely negatively correlated with mortality trend in the long term.

6.14 In the short term, mortality and sickness, and therefore health claims, can be positively correlated for some health insurance portfolios in some countries.

6.15 Mortality and morbidity calamity are highly correlated as they are the result of the same or similar causes.

6.16 Short term and long term type risks generally have low correlation to each other due to the fact they are manifest in different periods of time, hence driven by different causes.

---

13 Some components of hospital cost tend to have much higher inflation rates than other components. For example the overall costs of surgical implants had explosive growth in the last decade of the twentieth century.
14 In many countries pharmaceutical costs have an extraordinary high inflation rate.

Appendix D  Market Risk

D.1. Definition of Market Risk

1.1 Market risk results from the volatility and uncertainty risk inherent in the market value of future cash flows from insurer assets and liabilities. Market risk is thus driven by exposure to movements in the level of financial variables. These include: stock prices, interest rates, exchange rates or commodity prices and the exposure of options in either the assets or liabilities to movements in underlying pricing variables such as movements in the actual or implied volatility of prices and options.

1.2 A related risk is liquidity risk, the risk that various events will require the insurer to attempt to liquidate various asset holdings prematurely on short notice and under unfavourable terms. A trigger for liquidity risk could be market risk, but other operational and policyholder behavior risk factors could be the trigger. The Working Party suggests that liquidity risk is better placed within Pillar 2 actions of the supervisor than to require a Pillar 1 requirement.

1.3 In addition to the volatility of market risk affecting the net market value of the insurer’s assets, market risk may also affect the liabilities (and net surplus position) as follows:

1. Changing asset yields will affect the market value of the liabilities through their effect on the rate(s) used to explicitly or implicitly discount the liability cash flows.

2. Changing asset returns (yields) may affect the amount and/or timing of future liability cash flows. Policyholders may be entitled to some form of profit sharing related to actual and/or historical asset returns. In this respect, the different types of ‘interest’ profit sharing within the global insurance market might be categorised into the following three groups:

   A. Profit sharing that is fully based on objective indicators of the performance of the capital market, e.g. an indicator of the actual interest rate level that is calculated and published periodically by a government agency, or a stock market index. The company may or may not actually be holding these asset referenced benchmarks to back the liabilities.

   B. Profit sharing that is somehow related to the actual performance of the company (‘performance-linked’), particularly with respect to the company’s investments. Note: This type includes the systems where the management is entitled to ‘declare the bonus rate’.

   C. Profit sharing that is related to the actual performance of the assets that are ‘locked-in’ at the policy holders discretion, i.e. policyholders themselves are, at least partially, responsible for the way their premiums are invested. Note: The typical example of this type of profit sharing in Life insurance is the profit sharing that is (implicitly) offered with Unit Linked/Universal Life (UL) products in Europe or variable (separate account) products in the US.

1.4 All three types of profit sharing may also include certain types of guarantees offered by the insurer, e.g. a bonus rate that will never be negative or a minimum level of the maturity benefit.

1.5 Changes in asset returns in the external market may affect the amount and/or timing of future liability cash flows by inducing policyholders to “arbitrage” the external returns with those available in the policy be either surrendering or paying additional premiums. (Note, this policyholder behavior may not always appear “rational” due to differing tax implications and liquidity/risk preferences of the policyholder.)
1.6 The following definition of market risk for insurers is proposed:

*Market risks relate to the volatility of the market values of assets and liabilities due to future changes of asset prices/yields/returns. In this respect, the following should be taken into account:*\(^{15}\):

- Market risk applies to all assets and liabilities
- Market risk must recognize the profit sharing linkages between the asset cash flows and the liability cash flows (e.g. liability cash flows are based on asset performance)
- Market risk includes the effect of changed policyholder behavior on the liability cash flows due to changes in market yields and conditions.

D.2 Types of Market Risk

2.1 The principal sources of market risk are:

- **Interest Rate Risk** - risk of exposure to losses resulting from fluctuations in interest rates.
- **Equity and Property Risk** - risk of exposure to losses resulting from fluctuation of market values of equities and other assets.
- **Currency Risk** - risk that relative changes in currency values decrease values of foreign assets or increase the value of obligations denominated in foreign currencies.
- **Basis Risk** - risk that yields on instruments of varying credit quality, liquidity, and maturity do not move together, thus exposing the company to market value variation that is independent of liability values.
- **Reinvestment Risk** - risk that the returns on funds to be reinvested will fall below anticipated levels.
- **Concentration Risk** - risk of increased exposure to losses due to concentration of investments in a geographical area or other economic sector.
- **Asset/Liability Mismatch Risk** - to the extent that the timing or amount of the cash flows from the assets supporting the liabilities and the liability cash flows are different (or can drift apart) the insurer is subject to asset/liability mismatch risk.
- **Off-Balance Sheet Risk** - risk of changes in values of contingent assets and liabilities such as swaps that are not otherwise reflected in the balance sheet.

2.2 Market risk can only be measured appropriately if the market value of assets, as well as the market value of the liabilities, is measured adequately. Market values of assets can generally be deduced from listings in the various securities markets. Due to the lack of a real market for insurance liabilities, the market value of insurance liabilities can be approximated through evolving market/fair value techniques. The concept of the ‘replicating (asset) portfolio’, defined in section 6.2, is a useful concept in measuring the market value of insurance liabilities.

2.3 In general, life and health insurers purchase assets to match their liabilities. Historically this has not been true for non-life insurers who tend to manage separately the results from underwriting and investments. While all of the assets of an insurer are available to provide against adversity, it is common risk management practice for insurers to implicitly or explicitly allocate their assets for one of the following purposes:

- To support insurance contract liabilities
- To represent economic capital
- To represent free surplus

\(^{15}\) This also includes the situation where policy benefits, e.g. pensions within Life insurance, are indexed to adjust for price or wage inflation (either ‘unconditionally’ or ‘conditionally’ depending on the available capital). In that case there is inflation risk. Note: Inflation risks related to Health and Non-Life insurance benefits or future internal expenses are ignored here, since they are considered as special types of ‘trend risks’ and ‘operational risks’ respectively.

Copyright © 2004 International Actuarial Association
2.4 Sizeable portions of an insurer’s liabilities can have durations comparable to readily available high quality liquid assets in the local market. In these situations it is possible to select assets whose cash flows can provide a very close match to the liability cash flows. In other words, a replicating portfolio of assets is available in the market. In this situation, market risk focuses on the volatility of the market value of the actual assets held and the market value of the replicating portfolio of assets and the ability of the insurer to manage that volatility. This type of market risk will be called Type A risk and it also includes the effect of volatility on an insurer’s stand alone surplus or economic capital assets.

2.5 The long-term duration of some insurance (especially life insurance) liabilities requires the consideration of long term rates of reinvestment since replicating portfolio assets of sufficient duration may not be currently offered in the market. Measuring market risk for these liabilities entails considerable uncertainty about the composition of the replicating portfolio and the manner of its reinvestment to mature the underlying cash flows. Lowered rates of reinvestment in the future are typically of concern. In addition, life insurance contracts may contain various complex, long term options and/or guarantees for which replicating market positions may not currently exist (e.g., death and maturity guarantees on variable annuity products). These latter two types of market risk will be called Type B risk.

2.6 The assets and liabilities of an insurer are subject to Type A and possibly Type B risk. Shorter term insurance contracts without complex to value embedded options or guarantees are subject to Type A risk. Long-term insurance contracts and/or those containing complex embedded options or guarantees may be subject to both Type A and Type B market risk.

D.3 Time Horizon

3.1 In contrast to market risk for banks, where the risk measurement time horizon is generally defined in terms of days or weeks, insurer market risk is more appropriately determined using a time horizon of one year. One year recognizes the generally less active trading environment of insurers with respect to their asset and liability cash flows. One year reflects a conservative view of the time required by a supervisor to assume control of the affairs of a weakened insurer. One year reflects a conservative view of the time required for an insurer to rebalance a mismatched portfolio of assets and liabilities (i.e., presuming replicating portfolio assets are available). Failure to rebalance such a portfolio within one year is more appropriately the subject of Pillar 2 type supervisory measures.

3.2 When the market risk of liabilities is compared with the market risk of the assets used to support them, the net market risk for these liabilities can be measured. This net asset/liability mismatch position is generally subject to specific asset/liability management (ALM) policies and procedures of the insurer. Type A risk is diversifiable to the extent that another manager could immediately eliminate the mismatch risk through rebalancing the portfolio.

3.3 The Type B market risk for cash flows which extend beyond the term of currently available replicating portfolio assets requires consideration of future reinvestment decisions and reinvestment rates in the future. To a certain extent, market risk for these liabilities involves systematic (undiversifiable) risk due to the limited availability of (parts of) the replicating asset portfolio or, at least, uncertainty about its composition. In theory, these risks must always be assessed for the full remaining term of the liabilities. The best fitting replicating portfolio assets must be reinvested in accordance with the insurer’s policies and practices with respect to investments so as to provide for the lengthy future cash flows. The requirement of a full term time horizon is considered necessary due to the considerable uncertainties involved in providing for future cash flows beyond the term of currently available replicating portfolio assets.
D.4 Confidence Level

4.1 The market risk capital requirements should be determined in a manner consistent with the overall goal for the confidence level of Pillar 1 capital requirements. For example, they could be determined for all risks such that there is a very high (e.g., 99% CTE) confidence level that the assets of the insurer would be sufficient in one year's time to provide for the policy liabilities determined one year later at a moderate (e.g., 75% CTE) level. In addition, a second condition may also be imposed, such as, if the present value amount of the policy liabilities determined at time zero for all future durations at a fairly high (e.g., 90 or 95% CTE) confidence level is greater, then this amount should be held.

D.5 Advanced Approach – Type A Risks

5.1 This section outlines the advanced approach to be used in determining a Pillar 1 capital requirement for Type A market risks. Type A risk may be present in any of the cash flow generating assets and liabilities of an insurer.

5.2 The most advanced approach for determining Type A risks would involve the use of risk models by the insurer. These models would need to satisfy the requirements of the supervisor as suggested elsewhere in the WP report. The market value of assets or liabilities with future cash flows can usually be determined with reference to the financial markets for similar or identical instruments. Similarly the volatility of their market value can also be deduced. For future liability cash flows, especially insurance contract cash flows, their market values and market value volatility can be approximated through evolving market/fair value techniques. The concept of the ‘replicating (asset) portfolio’, defined in section 6.2, is also a useful concept in measuring the market value of insurance liabilities.

5.3 Market risk should include provision for both specific risk (e.g., perhaps as implied by the credit spread inherent in the yield of securities offered by the issuer) and general market risk (e.g., general sensitivity to future rates of return).

5.4 Market risk can be determined by modelling cash flows over a broad range of economic scenarios using stochastic modelling for the time horizon specified and the confidence level desired. The time horizon for this modelling would be one year at a high (e.g., 99% CTE) confidence level.

5.5 In situations where the insurer has a block of insurance contracts which exhibit only Type A market risk, the insurer may choose to conduct integrated modelling of the projected future cash flows resulting from the insurance contracts and their matching assets. Such modelling must reflect the actual asset allocation, reinvestment policies and practices of the insurer for that business. At the end of the one year time horizon, the reinvested matching assets must be sufficient to mature the then remaining liabilities with a prudent level of confidence (e.g., 75% CTE).

D.5.1 Practical Approximations

5.6 These might be considered by supervisors depending on their local circumstances and the appropriateness of the approximation.

- Allow for the use of a deterministic liability basis at the end of the one year horizon (rather than a multi-scenario or stochastic model approach at the 75% CTE level).
- Replace the stochastic modelling during the one year horizon with a series of deterministic scenarios designed to stress test economic scenario shocks at the 99% CTE level. Stochastic modelling of the resultant shocked portfolio after one year would then be required at the 75% CTE level.
D.6 Advanced Approach – Type B Risks

6.1 This section outlines the advanced approach to be used in determining a Pillar 1 capital requirement for Type B market risks. Type B risk may be present in any of the cash flow generating assets and liabilities of an insurer.

6.2 The most advanced approach for determining Type B risks would involve the use of risk models by the insurer. These models would need to satisfy the requirements of the supervisor as suggested in this report. Many of the same modelling requirements outlined for Type A risks are also applicable to Type B risks.

6.3 The appropriate time horizon for measuring this type of market risk is the entire duration of the (longer and containing complex options) liability cash flows. The general market risk component can best be measured at an advanced level through modelling of the insurer’s actual reinvestment policies and practices. Separate provision need also be made for specific risk inherent in the asset and liability cash flows. Specific risk results from an adverse movement in the price of an individual security owing to factors related to the individual issuer. The confidence level chosen will be the greater of 2 options:

- A very high (e.g., 99% CTE) confidence level that the assets will be sufficient in one year's time to provide for the policy liability cash flows determined at a moderate (e.g., 75% CTE) level at that time.
- A fairly high (e.g., 90 or 95% CTE) confidence level that the assets will be sufficient to provide for all future policy liability cash flows.

The following sub-sections describe in considerable detail the level of sophistication needed for the advanced approach.

D.6.1 Modelling Process

6.4 The modelling process begins with an identification of the assets and liabilities to be modelled. In particular, the process for generating their future cash flows under varying economic scenarios must be understood (i.e., the impact of embedded options). For this to be possible, the primary risk factors affecting market risk must be identified (e.g., interest rates, equity returns, property values, inflation etc.), and defined for their impact on policyholder and company behaviors/strategies. This must then all be modelled as part of an integrated set of economic scenarios. If the market risk for the liabilities is to be determined separately from the actual assets used to support them, then the concept of a replicating portfolio of assets will need to be employed. The combined asset and liability future cash flows will need to be modelled in an integrated manner to allow for a) asset/liability linkages, b) pass-through of risks to policyholders, c) reinvestment strategy and practices and d) impact of economic scenarios on policyholder behavior. The range of scenarios tested (e.g via deterministic or stochastic modelling) will enable the market risk for Type B risks to be determined.

6.5 The modelling process to determine the market risk of insurers may differ from that employed by the banks in a number of ways. Some of these differences are shown in the table that follows.

D.6.2 Replicating Portfolios

6.6 The general approach to determining market risk requires the modelling of the reinvestment of the relevant cash flows in accordance with the insurer’s investment policies and practices over an appropriate time horizon, using a range of economic scenarios to a high degree of confidence.

6.7 For cash flows whose duration does not extend beyond the replicating portfolio horizon (i.e., the longest duration, publicly available, debt instruments), the appropriate time horizon (as stated above) for modelling investment management behavior is one year. This is the Type A aspect of market risk.

6.8 For cash flows whose duration extends beyond the replicating portfolio horizon (primarily some types of insurance liabilities), the appropriate time horizon for modelling investment management behavior is the entire duration of those future cash flows. These cash flows are subject to both Type A and B aspects of market risk.

6.9 The difference between market risk determinations for general market interest rate risk for two sets of future cash flows, one slightly shorter than the replicating portfolio horizon and the other slightly longer, will be minimized the more accurately the investment practices of the insurer can be modelled.

6.10 In principle, the replicating portfolio generates cash flows that ‘replicate’ (i.e. coincide with) the annual liability cash flows in each individual future year. Therefore, the replicating portfolio provides a perfect ‘hedge’ against the liability risks.

6.11 Obviously, this is a theoretical concept. Liability cash flows are subject to several types of risks (e.g. mortality risks) that cannot be hedged by financial instruments. Therefore, the following definition of the replicating portfolio is proposed:

*The replicating portfolio (only) replicates the liability cash flows that are (‘risk’-) adjusted for the systematic non-financial risks, while volatility due to diversifiable non-financial risks (e.g. volatility risk as a consequence of mortality) is fully ignored.*

6.12 Consequently, the replicating portfolio should provide a full hedge against the financial risks that may affect future insurance liability cash flows before the replicating portfolio horizon.

D.6.3 Embedded Options

6.13 The replicating portfolio (i.e., the asset portfolio used to represent the future cash flows, should include specific financial instruments that provide a full hedge against (financial) ‘embedded options’ like minimum investment return guarantees related to profit sharing (if offered by the insurer).

6.14 Guarantees always offer additional value to the policyholders, since they indicate, implicitly or explicitly, that certain risks are transferred to the insurer. Therefore, they always increase the market value of the liabilities. Theoretically, the market value of these guarantees is equal to the market value of the financial instruments that are necessary to hedge these guarantees.

6.15 As these instruments are generally specific types of options or, if the guarantees also apply to future premiums, swaptions, their market value can generally be approximated by applying calibrated Black-Scholes types of option-price formulas; see e.g. Bouwknecht and Pelsser (2002) regarding annual minimum investment return guarantees for traditional Dutch regular premium business with profits, and Nonnenmacher and Russ (1997) for rather complex minimum investment return guarantees in German UL-business. If so, it will also be possible to measure the sensitivity of these market values to changes in asset yields. Therefore, including these

---

16 Alternatively, a so-called deflator approach may be useful (see e.g. Jarvis et al., 2001). However, this methodology is still very much under development.
instruments in the replicating portfolio allows for the sensitivity of the total market value of the replicating portfolio with the sensitivity of the future cash flow stream being measured.

6.16 One final consideration/note is that many contracts also contain embedded options which can be exercised by the insurance company. These options will then, obviously, always reduce the market value of the liability.

D.6.4 Incompleteness of the Capital Market

6.17 Unfortunately, investment return guarantees in life insurance products are often complex. As a consequence, financial instruments to hedge the corresponding risks are generally not amply available. These instruments may even be non-existent in practice. Nevertheless, it may still be possible to approximate their market values by applying option-pricing theory. Alternatively, their market values may be approximated through stochastic simulation using a combination of currently available financial instruments.

6.18 In some cases, insurers have only expressed the intention, not the guarantee, to cover certain risks or to provide a certain minimum level of profit sharing. For example, some life insurance benefits are ‘conditionally’ indexed for price or wage inflation. Some performance-linked with profits business may offer positive bonus rates if the financial condition of the company, as assessed by management, allows for the extra pay-outs. Such embedded options have a positive value to policyholders. In some cases policyholders’ expectations in this regard may be granted in court even if the conditions for their granting are not satisfied\(^\text{17}\).

6.19 Some life insurance liabilities may extend more than 30, possibly even 80, years into the future. This is much longer than the longest term of fixed-interest securities purchasable in the capital market (generally somewhere between 20 and 30 years for mature and developed investment markets). In these cases the insurer faces non-avoidable (systematic) reinvestment risks in the long term (i.e., Type B aspect of market risk). The present value of these liability cash flows far into the future can always be determined through modelling of the reinvestment policies and practices of the insurer in to the future using currently available financial instruments.

D.6.5 Economic Scenarios

6.20 In developing appropriate economic scenarios the following desirable characteristics of the constructed scenarios are noteworthy:

Interest rates
- Nominal yields must remain positive and not increase indefinitely
- Are subject to mean reversion but the reversion target is not constant
- Rate volatility decreases with maturity
- Higher volatility occurs with higher rates
- High correlation between maturities
- Distinctive yield curve shapes

Equity returns
- Negative skewness
- Fat tails over short periods
- Volatility clustering
- Exogenous shocks
- Markov property; only the current state is important
- Market correlations increase under extreme conditions

\(^{17}\) The Dutch insurance supervisor (PVK) has described such insurance liabilities recently as ‘soft’ liabilities. A possible way to handle them may be to assess them in a less quantitative and more qualitative way within the second pillar of supervision (the ‘supervisory review process’).
- Price appreciation versus dividend income

Inflation
- Non-persistence of extremely high or low (negative) inflation
- Realized may equal expected plus exogenous shock
- Mean reversion but target does not appear to be constant
- Volatility clustering
- Various forms of inflation
- Relationship to other economic factors

D.6.6 Discount Rates

6.21 The market value of a replicating portfolio can be determined by discounting their cash flows using appropriate discount rates. Assuming these cash flows correspond with the liability cash flows that are adjusted for the systematic non-financial risks, and ignoring the diversifiable non-financial risks as advocated before in section 3, the discount rates can be set equal to the actual risk-free spot yields. This approach implicitly provides for the specific risk of the issuer of the cash flows and allows the liquidity premia preferences in market yields to emerge over the life of the cash flows. Readers of this report should note that widespread market discussion on the proper allowance for these two aspects of market yields is on-going.

6.22 The use of different spot yields by different insurance companies should be avoided. It may be prudent for national insurance supervisors to prescribe the levels of the risk-free spot yields to be used for discounting the replicating asset cash flows within the process of determining solvency requirements. Of course, this requires an adequate procedure for estimating periodically the actual risk-free spot yield curve. For this, several methods are available. We mention the specifications that were proposed by Nelson and Siegel (1987) and Svensson (1994, 1995). For instance, the Nelson-Siegel approach implies estimating the following (non-linear) specification:

\[
\begin{align*}
    r_t^{\text{spot}} &= \beta_0 + (\beta_1 + \beta_2) \cdot \frac{1 - \exp\left(-\frac{t}{\tau}\right)}{\tau} - \beta_2 \cdot \exp\left(-\frac{t}{\tau}\right) \\
\end{align*}
\]

6.23 The parameters to be estimated are \(\beta_0, \beta_1, \beta_2\) and \(\tau\). Nice characteristics of this specification are:
- the specification is reasonably parsimonious
- the spot yield for the very short duration is equal to \(\beta_0 + \beta_1\)
- the estimated spot yields for the long term converge to \(\beta_0\).

6.24 Alternatively, the so-called splines methodology is also broadly applied in practice, particularly by central banks and asset management departments of banks and (larger) insurance companies. See Anderson & Sleath (2001) for a recent comparison and assessment of the Nelson-Siegel-type and splines-type methods.

D.7 Standardized Approaches – Type A Risks

7.1 This section outlines standardized approaches to be used in determining a Pillar 1 capital requirement for Type A market risks. Type A risk may be present in any of the cash flow generating assets and liabilities of an insurer.

7.2 Market risk should include provision for both specific risk (e.g., perhaps as implied by the credit spread inherent in the yield of securities offered by the issuer) and general market risk. (e.g., general sensitivity to future rates of return).
7.3 As described earlier in section 5, Type A risk can be determined using an advanced approach by modelling cash flows over a broad range of economic scenarios using stochastic modelling with a one year time horizon and a high (e.g., 99% CTE) confidence level. This section outlines some standardized approaches which may be considered as approximations for measuring market risk. The appropriateness of these approximations will be highly dependent on local country circumstances and the specific risk profile of the insurer.

D.7.1 Methodology

7.4 The essential ingredients required to assess Type A market risk are,

- Projected future cash flows
- Nature of embedded options
- Time horizon
- Confidence level
- Current economic scenario
- Series of adverse scenarios

7.5 Approximations can be made with respect to these ingredients to simplify Type A risk determination. The result is a range of standardized approaches from the most elemental to approaches which closely compare to the advanced approach.

7.6 One such approximation might use option adjusted durations to represent the price sensitivity of cash flows, the current market value of future cash flows and a set of investment return shocks. The shocks would need to be designed to reflect the time horizon and confidence level desired as well as the possible pattern of adverse scenarios. In this regard, it may be desirable to recognize the more active investment management conducted on closely managed blocks of business (i.e., when the active management holding period is less than the standard one year time horizon).

7.7 Another approximation might require the grouping of future cash flows into various term “buckets” (BIS uses the term “maturity method”). The sum of the cash flows in these “buckets” would be multiplied by factors to produce the capital requirement. These factors would, in theory, represent a combination of the above basic ingredients (i.e., time value of money from current economic scenario, adverse shock for desired confidence level and time horizon etc.). This type of approach is currently used by the BIS in their standardized approach for banks.

7.8 A very simple approximation (which depends heavily on broad decisions about the industry’s generalized exposure to Type A risk) is to simply multiply the balance sheet value of insurer assets and liabilities by a table of factors reflecting the presumed presence and size of Type A risk.

7.9 The relative merits of each type of approximation need to be viewed by the supervisor in light of local conditions, expertise and inherent industry risk. Objectivity and ease of calculation need to be balanced with greater accuracy, complexity and the overall impact of the method chosen on the management of market risk by insurers and the types of products that are offered in the market place.

7.10 To develop standardized approaches for market risks (or other risk for that matter) requires judgement and supervisory tradeoffs depending on the supervisors choice of approximation and its method of application. Ideally, the conservatism inherent in a standardized approach should incent insurers, as they are able, to use more advanced methods in the future. One possible concern in designing approaches which allow judgement to be used by the insurer (e.g., if the degree of market risk is subject to the asset allocation practices of the insurer) is that the results will be less transparent since there may be opportunities for the insurer to ‘manipulate’ the resulting solvency requirement. It is important for the supervisor to consider in advance the possibilities and significance of such self-selection. For example, the concern surrounding asset
allocation “games” can be addressed directly through a requirement that asset allocation for purposes of the capital requirement must coincide with the insurer’s management of their business.

7.11 Particularly in life insurance, some market risk from the total asset portfolio may be transferred to policyholders. This is generally the case in Universal Life business and many forms of adjustable and “with profits” business. Clearly, such assets and the corresponding liabilities should be closely matched (ignoring the non-financial diversifiable risks that may affect these liabilities) and the degree of such sharing of market risk needs to be reflected in the chosen standardized approach.

7.12 The following sub-sections outline some important aspects in selecting a standardized approach for certain sources of market risk as well a possible treatment of dependencies.

D.7.2 Fixed Interest Securities and Liabilities

7.13 The risk of fixed-income investments depends on some properties of these investments. The relevant properties are duration (the sensitivity against an interest rate increase) and rating (which matters for assessing the credit risk). Aside from ordinary bonds, there are mortgage-backed and asset-backed securities, which behave similarly, except for prepayments in a period of falling interest rates. Bonds denominated in a foreign currency are affected by the foreign exchange (FX) risk.

7.14 The market risk for fixed income investments is dominated by the risk of increasing interest rates. When the relevant interest rates (or the whole yield curve) increase by one percent, the value of a bond (portfolio) decreases by the amount of duration times 1%. The duration can either be exactly computed from the cash flows of the bond and the current zero-coupon yield curve, or it can be approximately assessed as 80% of the mean time to maturity. 

Example: a bond with a time to maturity of 10 years will lose about 8% of its value when the interest rate level increases by 1%.

7.15 The classical standardized approach to calculating a mismatch position is to employ a Macaulay duration analysis. This approach has a number of drawbacks. We mention three of them:

a. The duration approach as described is based on a first-order Taylor approximation of the interest sensitivity of the present value. This approximation is not very good for larger interest changes. A better approximation is possible by including the second-order term, i.e. the so-called convexity.

b. More importantly, the duration approach assumes a parallel shift of the spot yield curve, while non-parallel shifts are equally possible, and possibly even more ‘dangerous’ for the company. Non-parallel shifts can be taken into account by applying the approach for some duration bands individually and summing the results. Such an alternative approach can also be considered as an approach that allows for correlations between the changes of the ‘average’ spot yields per duration band that are less than one.

c. Still requires a fair degree of complex modelling by the company.

7.16 To assess market risk, requires the probability distribution of interest rate changes over a time horizon. This can be done through a statistical analysis of empirical economic data. The variance of interest rate changes is slightly higher for short maturities than for long ones, and higher for currencies with a high interest rate level than for low-interest currencies.

As a very rough estimate for major currencies, the standard deviation of yearly interest rate changes is of about 1.25%. Thus we obtain an approximate standard deviation of the yearly value change:
If this approximation is used instead of a detailed statistical calculation, it should be loaded with a prudent factor. The formula can be applied to whole portfolios, not only individual bonds, as the risk reduction due to diversification between bonds is rather small. When aggregating bond portfolios, we add $\sigma_{bond}$ values rather than $\sigma_{bond}^2$ values (which would apply if bond returns were independent).

Changes in bond yields may be caused by changes in the underlying risk-free rates, changes in the spreads that reflect the liquidity risk and credit risk of the asset, or changes in both components simultaneously. In section 3.4 we already suggested that the replicating asset portfolio (i.e. the liability cash flows) should be valued by discounting its cash flows on the basis of the risk-free spot yields. Consequently, changes in spreads only affect the market value of the actual assets available, while changes in risk-free rates affect both the market value of the assets available and the market value of the replicating portfolio (liabilities). It may be more logical to consider changes of spreads as typical forms of credit risk.

If a bond is denominated in a foreign currency, the volatility of the corresponding FX rate has to be accounted for. A typical yearly standard deviation for returns of a freely floating foreign exchange rate is around 10%. Thus we obtain

$$\sigma_{FX} \approx 0.1 \cdot assetValue$$

Again, this may be either used with a conservative factor or replaced by a statistical assessment.

The two risk components $\sigma_{bond}$ and $\sigma_{FX}$ can be combined as described in Section 3.4.1:

$$\sigma_{foreignBond} \approx \sqrt{\sigma_{bond}^2 + \sigma_{FX}^2} \approx \sqrt{\frac{meanTimeToMaturity^2}{100^2} + 0.01}$$

In this case, assuming zero correlation between the factors, is conservative. K. Froot (“Currency hedging over long horizons”) and others have shown that foreign assets tend to have a lower variance than the formula indicates, especially in the long run.

The formulas for $\sigma_{foreignBond}$ and $\sigma_{bond}$ can be used as pieces in a large, multivariate normal model. They describe the risk of stand-alone bond portfolios. However, in the case of asset-liability matching, the true risk may be smaller. If the times to maturity match the expected times of claim payments, and the assets in foreign currencies match foreign liabilities, the total value of assets and liabilities may become more immune against market fluctuations. Of course, an insurance company has some invested surplus capital in excess of the expected liabilities, which has the full market risk. Exact calculations are only possible with a full ALM model.

Equity and property positions are subject to Type A market risk when these assets are used to fund similarly performing policyholder liabilities (e.g., unit linked funds with no material guarantees) or represent free surplus. In these situations, market risk results from short term volatility in the market value of the underlying assets. The longest time horizon to be considered in this case (as discussed earlier) is one year. Shorter time horizons based on local products or conditions might be considered by local supervisors.

The variance of equity returns has been analyzed in numerous studies. The volatility (= annual standard deviation) is higher than for bonds. Even for the best diversified portfolios as
represented by index-tracking portfolios, the standard deviation of yearly returns may easily be
20% of the asset value. For individual equities of reasonable quality, it may be about 30%. Some
individual equity titles may have distinctly higher risks. These risks have to be quantified, based
on empirical data.

7.26 If equity is denominated in foreign currency, the standard deviation is

\[ \sigma_{\text{foreignEquity}} \approx \sqrt{\sigma_{\text{equity}}^2 + \sigma_{\text{FX}}^2} \]

7.27 As discussed for fixed income, this is a conservative formula. Foreign equity investments often
have a standard deviation of returns lower than this, mainly in the long run.

7.28 When aggregating equity investments of different currency zones, we should add their standard
deviations, assuming total dependence, rather that adding the squares (assuming independence).
This conservative assumption may be refined by a detailed analysis of correlations between
equity indices of different countries.

7.29 Real estate investments can exactly be treated as equity. Real estate indices take the role of
equity indices. The diversification between different countries may be slightly stronger than the
analogous diversification effect for equity.

7.30 Real estate prices tend to increase when mortgages are becoming cheap, i.e. when interest rates
fall.

D.7.4 Derivatives and Embedded Options

7.31 In sections 3.1 and 3.2 we already stressed the need to value embedded options explicitly. In
particular, their value should be set equal to the actual market value of the assets needed to hedge
these options. However, these assets may not be actually available. Therefore, in that case, special
attention is needed for possible mismatches between the options that are embedded in liabilities
and the derivative assets that are intended to cover them. The solvency requirement defined for
this should be equal to a conservative estimate of the possible change of the difference between
their market values. While these market values should always take the full remaining terms of the
contracts into account, the mismatch buffer only needs to cover the possible change of its
difference within the limited time period under consideration (one year).

7.32 Generally, calculating a mismatch provision for embedded options will not be an easy task. If it is
possible to get a reasonable approximation of their actual market value, i.e. the market value of
the replicating asset portfolio, by applying a (calibrated) Black-Scholes type of formula, it will
generally also be possible to get a reasonably conservative estimate of its possible change. Such
formulas generally have two types of parameters, namely the risk-free rate(s) and the implied
volatility. For complex options, the market value of the embedded options can only be reasonably
estimated by running stochastic simulations.
D.7.5 Other Types of Assets

7.33 Asset portfolios may contain many other types of assets. Some of them may even be off-balance sheet items. Typical examples are investments in private equity, commodities and all kinds of derivatives that are not intended to hedge options embedded in the liabilities. As with equity and property investments, the relating market risks are (generally) ‘asset-only’ risks. Therefore, the corresponding mismatch provision can be calculated similar to the way it is calculated for equity and property investments.

7.34 Some of these assets may only be available ‘over-the-counter’ and are hence, illiquid. In this situation, both their actual market values and the possible change of these values within the limited time period (one year) have to be estimated conservatively.

D.7.6 Currency Risk

7.35 Currency risk is important if not all assets and liabilities are denominated in the same currency. A solvency requirement for currency risk can be defined in a similar way as for equity and property risks (i.e., by setting it equal to the actual market value of the assets denominated in foreign currency times a conservative estimate of the potential change of value within the first next year). The ‘potential change’ factor can include the effects of both the potential change of the yields (prices) and the potential change of the currency.

D.7.7 Dependencies

7.36 Dependencies between asset market prices/yields of different asset types, particularly fixed-interest, equity and property (but excluding derivatives) are generally low. Correlations between prices/yields/returns of assets in local currency and those of assets that are denominated in foreign currency may be anything between $-1$ and $+1$, depending on the global and local economic conditions, the type of asset and the specifics of the assets (industry). It may therefore be reasonable to assume zero correlation between all these asset types in a factor-based approach. Consequently, the total solvency requirement for market risks can be set equal to the square root of the sum of squared requirements for these individual asset classes.

7.37 Of course, market prices of derivatives, including those that hedge options that are embedded in the liabilities are closely linked to the market prices of the underlying assets. Therefore, as mentioned before in section 5.2.3, it is very important to have consistency between the approaches for the ‘leading’ assets and the derivatives. In particular, if the approach for leading assets is based on an assumed change of the price/yield, the same change should be assumed in determining the change of the value of the derivatives. The resulting solvency requirement can be aggregated into the total requirement by simply adding it to the total defined in the foregoing paragraph.

7.38 Correlations within individual categories are generally high. Implicitly, this is taken into account by defining and summing different solvency requirements for different asset categories, instead of defining and summing them for individual assets. Any ‘extra’ correlations due to possible concentration within categories, e.g. many investments in shares of the IT-industry, can be ‘penalised’ by adding solvency requirements for concentration risks.

7.39 However, within the category of fixed-interest securities, special attention is needed for correlations between spot yields for different durations (maturities), if the factor-based approach for fixed-interest securities is applied to individual duration bands independently (see also section 5.2.1). In that case a choice has to be made for the way the corresponding solvency requirements are combined into one requirement for all fixed-interest securities (better: $S^{(fix)}$). This issue is
closely linked to the correlations issue. Spot yields for different durations are generally highly, but not perfectly, correlated. Therefore, the actual spot yield curve may also show non-parallel shifts. The following approach per duration band allows for such shifts:

1. Select a number of (modified) duration bands, e.g. 0-2 years, 2-5 years, 5-8 years, 8-12 years, 12-16 years, 16-24 years, and more than 24 years, with corresponding ‘median’ durations \( \text{dur}^{(1)} = 1 \), \( \text{dur}^{(2)} = 3.5 \), \( \text{dur}^{(3)} = 6.5 \), \( \ldots \), \( \text{dur}^{(7)} \) = say 28 and corresponding actual (risk-free) spot yields \( (r^{(1)}, r^{(2)}, \ldots) \) according to the actual risk-free spot yield curve.

2. Define ‘maximum’ potential absolute changes of spot yields that may occur within the first next year, for each of the individual spot yields individually \( (\Delta r^{(1)}, \Delta r^{(2)}, \ldots) \). Preferably, these are based on an analysis of historical changes for each of the spot yields individually.

3. Allocate the cash flows of the available fixed-interest securities and liabilities respectively to the different duration bands, calculate the actual market values as well as their balance per duration band \( (S^{(\text{fix})(1)}, S^{(\text{fix})(2)}, \ldots) \) and define the solvency requirement for each duration band \( i \) as \( \text{Solv}^{(\text{fix})(i)} = \text{ABS} \{S^{(\text{fix})(i)} \times \text{dur}^{(i)} \times \Delta r^{(i)}\} \).

4. Finally, define the total solvency requirement for fixed interest securities (balanced with the liabilities) as the sum of the requirements for the individual duration bands:
   \[ \text{Solv}^{(\text{fix})} = \sum_{i} \text{Solv}^{(\text{fix})(i)} \]

7.40 This way, implicitly, it is assumed that each of the individual spot yields may either rise or fall within the next year. In this respect zero correlation between individual spot yields is assumed. Therefore, the final outcome of this approach may be higher than the outcome based on a rise or fall of all spot yields at the same time (by \( (\Delta r^{(1)}, \Delta r^{(2)}, \ldots) \) or \( (-\Delta r^{(1)}, -\Delta r^{(2)}, \ldots) \) respectively), as it allows for non-parallel shifts. However, by simply summing the resulting individual solvency requirements we implicitly assume correlations to be equal to one.

7.41 Finally, this approach can be considered as a mix of duration matching and cash flow matching. The more different duration bands are distinguished, the more it will stimulate insurers to do actual cash flow matching.

D.8 Standardized Approaches – Type B Risks

8.1 By definition the development of standardized approaches for capturing Type B risks is fraught with difficulty. Where these risks are material in an insurer, the supervisor should encourage or even require the insurer to perform appropriate advanced approaches to modelling their Type B market risk.

8.2 Standardized approaches to assessing Type B market risk might include:

1. For long term interest guarantees in life insurance and annuity products the present value of future liability cash flows must be determined on the presumption that long term reinvestment returns revert to a conservative view of historical long term averages.
2. For complex options, appropriately conservative factors must be derived based on rigorous stochastic modelling of industry wide data to adequately capture the tail of the loss distribution for the confidence level required.

APPENDIX E  Credit Risk

E.1 Definition of Credit Risk

1.1 Credit risk is the inability or unwillingness of a counterparty to fully meet its on and/or off-balance sheet contractual financial obligations. The counterparty could be an issuer, a debtor, a borrower, a broker, a policyholder, a reinsurer or a guarantor.

1.2 Credit risk has been traditionally associated with assets. However, it can exist with respect to any set of projected future cash flows. Credit risk is therefore also important in assessing the true relief provided by a counterparty to an insurance transaction, such as reinsurance or a party to whom the insurer has outsourced some of its work functions. Credit risk might even be considered to exist in regard to the projected future cash flows resulting from the policyholder obligations. This latter aspect of credit risk is quite controversial as it suggests the value of policyholder obligations diminishes as the credit risk of the insurer declines. The WP recommends that insurer capital requirements for credit risk do not reflect the potential ability of the insurer to default on its own cash flows.

1.3 Credit risk can be reflected in the present value of a set of cash flows either implicitly via a credit risk spread incorporated in the discount rate or via explicit modelling of the cash flows themselves.

1.4 The market value of a stream of projected future cash flows (e.g., a bond) reflects the current market view (among many things) of the credit risk of the provider of the cash flows. Such a view might reflect a variety of market knowledge of the bond issuer such as credit ratings provided by various agencies. Necessarily, such a view will likely reflect the current financial position of the issuer as well as the current economic environment. Such a view will consider the possibility of the issuer slipping in its ratings (i.e., ability to pay) as well as the probability of default (PD) and the amount of loss given that default occurs (LGD).

1.5 The Bank for International Settlements (BIS) defines the capital requirements for banks. In particular, its April 2003 consultative document entitled “The New Basel Capital Accord” contains extensive materials related to the determination of credit risk capital requirements, including both standardized and advanced approaches. The WP recommends that similar approaches be used for insurers. The WP recommends that the BIS approach may require some modification to address insurer specific issues. These modifications are noted throughout this portion of the WP report.

E.2 Types of Credit Risk

2.1 The principal sources of credit risk are:

- Direct Default Risk: risk that a firm will not receive the cash flows or assets to which it is entitled because a party with which the firm has a bilateral contract defaults on one or more obligations.
- Downgrade or Migration Risk: risk that changes in the possibility of a future default by an obligor will adversely affect the present value of the contract with the obligor today.
- Indirect Credit or Spread Risk: risk due to market perception of increased risk (i.e., perhaps due to business cycle or perceived credit worthiness in relation to other market participants).
- Settlement Risk: risk arising from the lag between the value and settlement dates of securities transactions.
• Sovereign Risk: risk of exposure to losses due to the decreasing value of foreign assets or increase the value of obligations denominated in foreign currencies.

• Concentration Risk: risk of increased exposure to losses due to concentration of investments in a geographical area or other economic sector.

• Counterparty Risk: risk of changes in values of reinsurance, contingent assets and liabilities (i.e., such as swaps that are not otherwise reflected in the balance sheet).

2.2 In general, life and health insurers purchase assets to support their liabilities. Historically this has not been true for non-life insurers where there has been a tendency for insurers to manage separately the results from underwriting and investments. While all of the assets of an insurer are available to provide against adversity, it is common risk management practice for insurers to implicitly or explicitly allocate their assets for one of the following purposes:

• support insurance contract liabilities
• represent economic capital
• represent free surplus

2.3 The allocation of assets to support specific policy liabilities is especially important for those insurance products whose performance depends directly on the performance of the underlying assets. In situations where the asset performance (including the impact of credit risk) is shared directly or indirectly with the policyholder, then appropriate credit can be taken in the determination of the credit risk capital requirement. Such credit must take into account policyholders’ reasonable expectations in this regard as well as the insurer’s practices in sharing such experience with policyholders.

2.4 Sizeable portions of an insurer’s liabilities can have durations comparable to readily available high quality liquid assets in the local market. In these situations it is possible to select assets whose cash flows can provide a very close match to the liability cash flows. In other words, a replicating portfolio of assets is available in the market. In this situation, credit risk focuses on the actual assets held and the ability of the insurer to manage its credit loss position within the replicating portfolio horizon. This type of credit risk will be called Type A risk.

2.5 The long-term duration of some insurance (especially life insurance) liabilities requires the consideration of long term reinvestment of existing assets since a replicating portfolio assets of sufficient duration may not be currently offered in the market. For this type of business appropriate account must be taken not only of credit risk in current assets (Type A credit risk) but also the credit risk involved with future reinvested assets as well. This latter aspect of credit risk will be called Type B risk. Assessing Type B credit risk entails considerable uncertainty about the composition of the replicating portfolio and the manner of its reinvestment to mature the underlying cash flows. The length of the reinvestment period may extend through several economic periods.

E.3 Key Drivers of Credit Risk

3.1 Some of the key drivers of credit risk include

• Credit quality – Credit quality of an investment or an enterprise refers to the probability that the issuer will meet all contractual obligations. This assessment normally occurs at both the initial investment and at each renewal point. One of the common measurements used in assessing credit quality is the rating assigned to the issuer. A variety of ratings agencies

---

18 Canadian Institute of Actuaries, 2003 Report of the CIA Sub-Committee on Credit Risk
provide these assessments to the public, giving the investor a perceived level of confidence in the issuer’s ability to make good on the repayment schedules to which it is committed.

- **Maturity** – The longer the term to maturity of an investment, the longer even a high quality issuer has to potentially deteriorate

- **Concentration by industry** – Conditions that trigger credit events have a tendency to impact on the entire economy simultaneously. Within this general characteristic, however, the impact of economic development often varies between sectors of the economy. Within a sector, however, there tends to be uniformity between the entities participating in that sector. Degrees of separation within a sector will exist, but these are on a smaller scale than those that normally occur between sectors.

- **Concentration by geography** – Credit risk has been shown to carry a large degree of contagion. Periods of relatively few credit events are followed by periods where default experience is extremely high. Similarly, economically depressed regions tend to produce high levels of default experience in comparison with more prosperous areas. That these regions can and do change over time creates a challenge to the process of credit risk analysis.

- **Size of expected loss** - The size of loss due to a credit event can vary widely, from loss of some or all of the return on an investment to loss of some, or all, of the inherent principal. Losses can also occur from a delay in the timing of a scheduled payment, causing either a loss of return during the deferral period, a reduction in available reinvestment rate during the deferral period, or both. When a scheduled payment is delayed for any reason, there is also the potential for an associated loss if the payment were needed to match a scheduled outflow. The investor would then be required to make good on its obligation by borrowing or selling other assets. They might need to delay payment of their own scheduled obligation, possibly incurring a penalty.

### E.4 Controls and Hedging Strategies

4.1 Important in the management of credit risk are a combination of sound underwriting practices and appropriate lending limits within the insurer.

4.2 A broad definition of hedging strategies used to offset credit risk would include

- letters of credit
- contingency deposits
- securitization of mortgages (Mortgage Backed Securities)
- securitization of other assets (Asset Backed Securities)
- credit derivatives
  - credit default swaps
  - total return swaps
  - collateralized debt obligations (CDOs)
  - credit-linked notes
  - credit spread options
  - basket derivatives

4.3 Investment performance features of some insurance products also permit some, or all (policyholder reasonable expectations may at issue), of the credit losses for assets deemed to be used to support the policyholder obligations of specific blocks of insurance products.
E.5 General Modelling Approaches

5.1 There are a number of generalized approaches that are used to model credit risk\(^1\). A few of them will be summarized in the following paragraphs.

5.2 In default models, the rates of default and recovery are modelled explicitly. Present values are taken using the risk-free interest rate curve, and different cash flows under assumptions of default or non-default are valued using probabilities.

5.3 For example, assume a $100 cash flow is expected in one year from XYZ Corporation. Their probability of default is known to be p, and recovery on default is expected to be R. The risk-free one-year rate is i. Then the current value of the cash flow is

\[
100 \frac{(1 - p)}{(1 + i)} + 100 \frac{p R}{(1 + i)}
\]

5.4 Estimates of R are very difficult, and so it is usually set to a constant around 40% to 50%, based on experience. Even most stochastic models take this approach. Values of p can be found for given credit ratings from the various credit rating agencies, and the combination of p and R can be compared to the spread of the corporation’s bonds for reasonableness.

5.5 In default models there are two states considered, either in default or not in default. Credit migration models consider not only the risk of default, but also the risk that an investment will lose (or gain) value due to changes in the corporation’s credit rating. For example, if you hold a bond rated AA and it is downgraded to A, the bond will lose value, since it will be less desirable to potential buyers. Central to all credit migration models is a matrix of values known as a transition matrix. The matrix contains the probability that a bond will change from its current credit rating to another credit rating.

5.6 Asset models were developed in the 1970’s by Merton. The general concept is that a firm will go into default if the value of its assets becomes less than the value of its debts, and so the firm’s debt can be modelled as an option against its assets. The basic approach developed by Merton has been considerably expanded since its initial introduction.

5.7 An asset model can be combined with a model of correlations between obligors to produce a portfolio-level risk management model. For example, correlations between different obligors’ underlying asset values are sometimes estimated by reference to correlations between stock prices. This approach underlies a number of commercially available credit risk models.

E.6 Degree of Protection

6.1 The credit risk capital requirements should be determined in a manner consistent with the overall goal for the degree of protection (confidence level) inherent in Pillar I capital requirements.

E.7 Time Horizon

7.1 Consistent with the time horizon for other insurer risks, credit risk should generally be determined using a time horizon of one year. One year recognizes the generally less active trading environment of insurers with respect to their asset and liability cash flows. One year reflects a conservative view of the time required by a supervisor to assume control of the affairs of a weakened insurer. One year reflects a conservative view of the time required for an insurer to address the credit risk in its assets. Failure to actively manage credit risk within such a portfolio within one year is more appropriately the subject of Pillar II type supervisory measures.

---

\(^1\) Recommended reading includes a paper from the Australian Institute of Actuaries, 2003 Capital Reserving for Credit Risk for Insurers (Life & GI) and Other Institutions. Online at [http://www.actuaries.asn.au](http://www.actuaries.asn.au)
7.2 This assessment time horizon should not be confused with the need to consider, in such an assessment, the full term of all of the assets and obligations of the insurer. For example, Type B credit risk requires consideration of future reinvestment decisions and future economic scenarios for the full term of the obligations of the insurer. Credit risk for these liabilities involves systematic (undiversifiable) risk due to the limited availability of (parts of) the replicating asset portfolio or, at least, uncertainty about its composition. In theory, these risks must always be assessed for the full remaining term of the liabilities. The best fitting replicating portfolio assets must be reinvested in accordance with the insurer’s policies and practices with respect to investments so as to provide for the lengthy future cash flows. The requirement of a full term time horizon is considered necessary due to the considerable uncertainties involved in providing for future cash flows beyond the term of currently available replicating portfolio assets.

E.8 Advanced Approach – Type A Risks

8.1 The BIS has developed considerable experience with respect to credit risk capital requirements in the banking sector. The WP believes that a similar approach should also be considered for use by insurers in capturing Type A credit risk.

8.2 In considering the applicability of the BIS approach, insurance supervisors will need to consider the appropriateness of several elements in the BIS approach. For example,

- **Degree of protection** – the WP recommends consistency throughout the Pillar I requirements
- **Time horizon** – the WP recommends consistency throughout the Pillar I requirements
- **Diversification** – the WP recommends insurers reflect the diversification in their portfolios
- **Correlation** – the WP recommends that consideration be given to allowing insurers to reflect their own asset correlations
- **Cycles** – the WP believes the use of “current” versus “through the cycle” distributions for the frequency and severity of default – the WP believes this issue requires further study
- **Migration** – the WP supports the use of credit migration techniques (non-absorbing hitting probabilities for rating migration events) in the framework

A General Approach

8.3 The following paragraphs outline a general approach to the modelling of Type A credit risk.

8.4 Corporate bonds involve credit risk. The value of such a bond shrinks if the rating of the issuing company falls. This is the downgrade risk or, more generally formulated, the credit spread risk. The most extreme case is default. Expected default probabilities are available from rating agencies.

8.5 There are several commercially available software products to assist in the modelling of credit risk. Some of these focus on default modelling only while others also include credit spread modelling as well. One product explicitly models transition probabilities between ratings, where the lowest level, the default, is an absorbing state.

8.6 A supervisory credit risk assessment guideline should be designed in way not to demand the use of commercial software packages or services. The proposed guideline should provide a simple formula that is compatible to the multivariate normal framework of the base-line approach. One such formula is proposed here.

8.7 In this simple credit risk model, a bond is essentially characterized by its mean time to payment $T$ and the current yearly default probability $p_1$ of the issuer. For rating BBB, for example, a typical yearly default probability is $p_1 = 0.2\%$. For assessing credit risk, we neglect the many
small cash flows due to coupon payments and assume just one large cash flow, the principal payment, at time now + $T$. The theoretical value of such a bond is

$$\text{assetValue} \approx (1 - p_T) \cdot \text{principal}$$

where $p_T$ is the default probability for the whole time period $T$. For the same period, the variance of the value change due to credit risk can be computed as

$$\sigma_{\text{credit}}^2(T) \approx p_T \cdot \text{assetValue}^2$$

8.8 The distribution function is binomial and has a form that is very different from normal. Another conservative assumption is that the corporate bond has a zero value after a default whereas, in reality, a small part of the face value may be recovered.

8.9 Our time horizon is 1 year, so we need the return variance $\sigma_{\text{credit}}^2 = \sigma_{\text{credit}}^2(1\text{year})$ due to credit risk, rather than just $\sigma_{\text{credit}}^2(T)$. This variance $\sigma_{\text{credit}}^2$ is affected not only by defaults but also by fluctuations in the rating of the issuer during the maturity period. A default-only model underestimates the variance. Rating fluctuations have to be included to arrive at estimated standard deviations that are large enough.

8.10 The model just assumes two things:

1. There is a rating scale on which the rating fluctuation can be described as a Brownian motion in a sufficiently good approximation.
2. There is a minimum value on this scale that corresponds to a default and serves as an absorbing state of the Brownian motion.

8.11 All the rest of the model can be derived from these two assumptions. The theoretical hitting probability of the absorbing state within a time interval $T$ is

$$p_T = 1 - \Phi \left( \frac{\text{const}}{\sqrt{T}} \right)$$

where $\Phi(.) = 2N(.) - 1$ and $N(.)$ is the cumulative standard normal distribution with unit variance. The constant depends on the initial rating, but does not matter here.

8.12 Now we can relate default probabilities for different time intervals:

$$p_T = 1 - \Phi \left[ \sqrt{\frac{1\text{year}}{T}} \Phi^{-1}(1 - p_1) \right]$$

where $\Phi^{-1}$ is the inverse function of $\Phi$, with $\Phi^{-1}(\Phi(p)) = p$. Given an annual default probability $p_1$, this formula allows computing the default probability $p_T$ of the same issuer over a time interval of size $T$, including the rating fluctuation effect.
8.13 The same model leads to an approximation formula for the yearly variance of returns due to credit risk:

\[
\sigma_{credit}^2 \approx \frac{1}{T} \frac{1}{p_T} \left\{ 1 - \Phi \left[ \frac{1}{T} \Phi^{-1}(1 - p_1) \right] \right\}
\]

or, as a numerical approximation in closed form,

\[
\sigma_{credit}^2 \approx \frac{1}{T} \frac{1}{p_1} \left[ \frac{1}{b} \left( \frac{1}{T} \frac{1}{\sqrt{c - \log p_1 - c + c} \cdot \log p_1 - c + c} \right) \right]^2
\]

with \( b = 2.37 \) and \( c = 0.85 \). This formula quantifies the credit risk of a bond as a function of its mean time to payment, \( T \), and the issuer’s current annual default probability, \( p_1 \).

8.14 As an example, we regard two BBB bonds. One has a remaining maturity of \( T = 1 \) year, the other bond has a maturity of \( T = 5 \) years. The issuer has a current annual default probability of \( p_1 = 0.002 = 0.2\% \). Using the formula above, the 1-year bond has a credit risk of

\[
\sigma_{credit} \approx \sqrt{0.002 \cdot \text{assetValue}} \approx 4.5\% \cdot \text{assetValue}
\]

For the 5-year bond, we obtain a credit risk of \( \sigma_{credit} \approx 18.3\% \cdot \text{assetValue} \). This higher value reflects the additional risk due to expected rating fluctuations over the 4 last years of the 5-year maturity period.

8.15 For a portfolio of different corporate bonds, there are diversification effects, which are limited by the fact that defaults may be correlated, depending on the geographical or economic proximity of the different issuers. In general, default frequencies also depend on worldwide economic cycles. In economically difficult times, many companies are subject to simultaneous downgrading or even default. There may be chain reactions in case of defaults. Statistics show that annual default frequencies exhibit a level of volatility distinctly higher than expected in a purely stochastic, Poisson-like world.

8.16 A simple, conservative model for the diversification is proposed. The credit risks \( \sigma_{credit,i} \) of all bonds are computed with the formula presented above. The maximum risk, for full dependence, is

\[
\sigma_{credit,\max}^2 = \left( \sum_i \sigma_{credit,i}^2 \right)^2
\]

8.17 In case of no dependence, we have

\[
\sigma_{credit}^2 = \sum_i \sigma_{credit,i}^2
\]
8.18 We conservatively assume that the best diversification can be approximated by correlation coefficients of 0.5. The resulting credit risk of a bond portfolio is

\[
\sigma_{\text{credit}}^2 = \frac{\alpha}{2} \sum_i \sigma_{\text{credit},i}^2 + \left(1 - \frac{\alpha}{2}\right) \left(\sum_i \sigma_{\text{credit},i}\right)^2
\]

where \(\alpha\) is the estimated degree of diversification. Bonds from the same issuer have \(\alpha = 0\), and an optimally diversified bond portfolio has \(\alpha = 1\).

8.19 Sophisticated software products explicitly model the dependencies between defaults. Chain reactions in case of defaults may lead to a fat tail of the true overall credit risk.

8.20 Eventually, we combine market and credit risk of a fixed-income portfolio:

\[
\sigma_{\text{fixedIncome}} \approx \sqrt{\sigma_{\text{bond,market}}^2 + \sigma_{\text{credit}}^2}
\]

assuming independence between bond markets on one hand and downgrades and defaults on the other hand. This assumption has to be checked and perhaps replaced be the more conservative assumption of a slightly positive correlation.

E.9 Advanced Approach – Type B Risks

9.1 Type B credit risk is inherent in insurance products of long duration (i.e., beyond the duration of current assets or replicating portfolio assets). Type A credit risk provisioning (e.g., as per the Basel Accord) only provides for the credit risk inherent in currently held assets.

9.2 If, in valuing the insurer’s assets and liabilities in accordance with a total balance sheet approach, the future policy liability cash flows are present valued using investment returns which are net of credit risk, then the present value amount of the policy liabilities so determined will include a provision for credit risk for the entire term of the liabilities.

9.3 The present value amount of this credit risk provision can be estimated through determination of the credit spread inherent in future investment returns. Care must be exercised to avoid double-counting the credit risk provision for Type A credit risk in both the liabilities and via direct reference to the current assets. Care must also be exercised that an appropriate provision for Type B credit risk has been made. If the credit spread assumed in the future simply reflects expected losses or simply the current position in the credit cycle, then it may be insufficient for solvency purposes.

E.10 Standardized Approaches – Type A Risks

10.1 The Working Party (WP) recommends that the work of the BIS with respect to credit risk capital requirements for banks be also considered for use by insurers in capturing Type A credit risk. In considering the BIS approach, insurance supervisors will need to consider the appropriateness of the time horizon and confidence level assumptions implicit in the BIS approach. Also to be considered is the appropriate treatment of policyholder pass-through features.
E.11 Standardized Approaches – Type B Risks

11.1 By definition the development of standardized approaches for capturing Type B risks is fraught with difficulty. Where these risks are material in an insurer, the supervisor should encourage or even require the insurer to perform appropriate advanced approaches to modelling their Type B credit risk.

11.2 Standardized approaches to assessing Type B market risk might include (from the simplest to the more sophisticated):

1. Where it is not possible to directly compute the present value of future liability cash flows, provision for Type B credit risk can be made approximately by applying a factor to the policy liabilities of long-term business. These factors would need to be tailored to the circumstances of an individual supervisor and their financial reporting structure for these liabilities.

2. Where it is possible to estimate the duration of long term business, provision for Type B risk can be made approximately by applying a credit risk spread to the duration (beyond that of the current assets) and the policy liabilities for long-term business.

3. Where it is possible to directly compute the present value of future liability cash flows, provision for Type B credit risk can be made directly through use of a credit risk spread.
APPENDIX F  Lessons from Insurer Failures

F.1  Lessons from Recent Insurer Failures

1.1  There have been a number of high profile insurer failures in recent years. Before attempting to identify the characteristics of a workable international risk-based solvency approach, it is worthwhile to examine the reasons behind the failures, to the extent possible at this stage. This will help focus the needs of the risk-based measures more closely. The WP also notes the Sharma Report, available from the Conference of European Supervisors which provides an excellent summary of the lessons learned from European insurer failures.

F.1.1  HIH Insurance (Australia)

Background:

1.2  The HIH Insurance Group (HIH) was declared provisionally insolvent in March 2001. Following investigation by the provisional liquidator, insolvency was confirmed in August of the same year. The estimate of the deficit in assets to support the outstanding liabilities is still uncertain, but the shortfall, estimated to be between A$3.5 billion and $5.3 billion in August 2001, appears to be firming up at a figure towards the middle of that range.

1.3  A Royal Commission was established to look into the reasons behind the failure. In April of 2003, the Royal Commissioner presented his report on the reasons behind the collapse and on recommendations to minimise the chance of future similar occurrences. His report focused on a failure by management to provide sufficiently for outstanding liabilities as the key reason for failure, compounded by “blind faith” in the leadership and an aggressive approach to growth. However, the report and the testimony from witnesses to the Commission provides a more detailed account, as follows.

Relevant Issues:

1.4  Firstly, HIH had a unique business spread. Its portfolios were predominately longer tailed and more risky than the market norm, despite more recent attempts to increase the shorter tailed business focus. The accompanying high volatility of outcomes accentuated the risk of failure.

1.5  HIH had been founded and led for many years by a strong-minded, goal-driven CEO. It emerged from the Royal Commission’s investigations that, whereas in the earlier years of the company’s history, this approach was very successful, the CEO’s approach had contributed to more recent problems.

1.6  In 1999, HIH completed the take-over of another major Australian based general insurer, FAI Insurance. It has emerged that the price paid for FAI was substantially greater than the net asset value. Indeed, in hindsight there are strong indications that FAI was technically insolvent, at the time of take-over. No due diligence was performed as part of the take-over procedure.

1.7  The evidence presented to the Royal Commission on claim reserving and management practices, raised questions as to the level of objectivity applied and the level of prudence. HIH management argued that risk margins in setting outstanding claim reserves were made unnecessary by the company’s outwards reinsurance program. This was shown to be a false security. Similarly, underwriting, risk pricing and premium setting practices came into question and in some areas were found to be deficient.
1.8 A number of connections between the company’s external auditor and HIH were highlighted by the Commission. As an example, the company’s CFO at the time of failure was previously a senior partner at the auditor as were several members of its board, including its Chairman. These connections caused questions to be asked about the level of independence, and hence effectiveness, of the auditor.

1.9 HIH was the major client of the external actuary who examined the long tailed claims portfolios. Fees from his work for the company represented the majority of his annual income. This put pressure on any statement regarding the actuary’s level of independence.

1.10 The Royal Commission unearthed a substantial dearth of data for actuarial, accounting and underwriting studies. Any such lack of reliable data would inevitably have led to an increase in the level of subjectivity for key decisions.

1.11 In the final years of the company’s life, it entered into “financial reinsurance” deals that demonstrably did not include a transfer of risk (because of the existence of “side letters” that precluded any claims), and hence were effectively loans. Whilst it could be argued that these deals did no more than delay the inevitable, they appear to have at least increased the size of the ultimate deficit.

1.12 The ambitious nature of the management approach created a strong “top line” (i.e. written, which may have increased the pressure on reserve adequacy and detracted from the need to protect “bottom line” results (i.e. net profit).

1.13 Although the Royal Commission clearly absolved the supervisor, APRA, from direct blame for the collapse, the report did highlight a number of areas where APRA’s access to relevant data and other information was lacking and which, the Commissioner argued, caused a delayed response.

1.14 Governance was found to have been wanting across a number of aspects of HIH’s operations, not the least being overseas subsidiaries and the underwriting of new lines of business.

1.15 The Australian supervisory requirements for general insurers have been renewed, and substantially upgraded with effect from 1 July 2002. Although already planned prior to the HIH failure, it can be argued that the final model was guided by an interpretation of the reasons behind the collapse in an attempt to prevent a repeat situation. In addition, the Royal Commissioner’s report included 61 recommendations, many of which have already been acted on by the Australian Federal Government.

F.1.2 Independent Insurance (UK)

Background:

1.16 Independent Insurance Plc was a UK based general insurer that specialised in general and public liability business transacted via intermediaries and as well as personal lines. The Company also participated in the London market by accepting lines on larger risks. Premium income was approximately £830m in 2000, however the company had expanded significantly in the year experiencing 64% growth in premiums. Approximately 75% of the written premium was in the hands of intermediaries at the end of 2000.

1.17 Independent Insurance was unusual in that since its floatation in 1993 on the stock exchange it had included an actuary’s opinion on the reserving adequacy in its published accounts. This is not a requirement in the UK and to date only a few companies have followed this practice.

1.18 In the late 1990’s there have been changes in the legal environment that have led to increased costs in settling liability claims. This has impacted the entire liability insurance market.
1.19 In May 2001 the Company’s actuarial advisers advised Independent's board that it could not form an accurate actuarial assessment of the insurer's reserves after discovery of claims that had not been entered into the company’s accounting systems. The Company was placed in provisional liquidation in June 2001.

1.20 The Serious Fraud Squad is investigating the circumstances surrounding the failure of the Company and therefore it will be some time before the full facts are revealed.

1.21 From press comment it appears that there were some very significant reinsurance contracts that were entered into by the Chief Executive without the full knowledge of the board.

**Reasons**  
- Rapid growth  
- Insufficient reserves  
- Failure to price adequately  
- Legal and claims environment changes  
- Ineffective corporate governance

**Warning Signs**  
- Dominant Chief Executive  
- Negative cash flow  
- Unidentifiable competitive advantage

F.1.3 **Equitable Life Assurance Society (UK) (“the Society”)**

**Background:**

1.22 Equitable Life is a mutual insurance company with assets in excess of £25bn that has been trading since the eighteenth century and ceased accepting new business in December 2000. Between 1957 and 1988 most of the Society’s new pensions policies included the right to use the fund built up to buy a pension on guaranteed terms (“GAR”). In 1978 legislation introduced Open Market Options (“OMOs”) for new retirement annuity contracts. These options gave the policyholder the right to purchase an annuity in the open market.

1.23 When interest rates are high the policyholders can buy the annuity from the open market or the Society and when interest rates are low they can buy annuities from the Society using their GAR option.

1.24 The Society believed at that time that these policies provided a minimum guaranteed level of cash benefit and a minimum guaranteed level of annuity to protect policyholders against very low or very high interest rates. It believed that, in times of normal interest rates, bonus rates could be adjusted to avoid either of these guarantees causing significant cost to the with-profits fund. The bonus consisted of regular bonuses and a final bonus when the annuity was taken.

1.25 In 1988 the Society ceased offering GARs, however the existing GAR policyholders had the right to invest new premiums under their existing contracts (Open-ended option).

1.26 In late 1993 annuity rates fell below those guaranteed in most GAR policies. The Society declared final bonuses so that the value of total benefits, including the value of the guaranteed annuity, was broadly equal to each policy’s notional share of the with profits fund (“asset share”). With lower annuity rates, the option to take a pension at the guaranteed annuity rate had significant value. If a policyholder chose not to take a GAR option, preferring the flexibility of an alternative option, then the benefits were of lower value. The Society believed that asset share should be delivered whichever option was selected. This led to a lower rate of final bonus for policyholders taking the GAR option than for those not using the GAR option.
In September 1998 a number of complaints were made to the Pensions Ombudsman as some policyholders believed that the Society’s stance was unlawful.

The High Court held that the Society’s Board had exercised its discretion as to final bonuses in a legally permissible manner. The Court of Appeal determined by a majority that it was not lawful to differentiate in this way within the group of GAR policyholders. It decided that GAR policyholders should receive the same proportionate final bonus irrespective of the form of the benefits taken (i.e. OMO or GAR option). The Court did not, however, decide that it was unacceptable for the Society to differentiate between GAR and Non-GAR policyholders in this respect. This allowed any cost of the GAR options to be “ring-fenced” to those policyholders with GAR policies. The Society appealed the decision to the House of Lords.

The House of Lords’ decision took matters beyond this by saying that the Society could not apply a different bonus policy to GAR and non-GAR policyholders.

Equitable’s solvency position and the decisions facing the prudential regulator FSA changed dramatically after the House of Lords’ judgement. FSA then had to decide whether to close Equitable to new business or to allow them to try to sell the company as a going concern. The prudential regulator’s primary objective was to protect existing policyholders’ interests by ensuring that Equitable remained solvent and able to meet their liabilities. FSA took the view that Equitable’s strategy of seeking a buyer was likely to result in the best outcome for policyholders. Equitable said, and FSA accepted, that a sale could result in Equitable acquiring sufficient funding to repay the seven months of bonus withheld in response to the House of Lords’ judgement, and possibly to make a goodwill payment to existing policyholders on top of that. That position could only be achieved - if at all - through a sale.

However, the Board was not able to find a purchaser and on 8th December 2000 the Society was closed to new business. Nevertheless a report from the Parliamentary Ombudsman in July 2003 ruled out any prospect of compensation on the basis of regulatory failure.

People who had Equitable Life with-profits policies in force on 8 February 2002, when Equitable’s Scheme of Arrangement came into effect, are covered by the terms of that scheme and are therefore unable to pursue complaints about mis-selling.

An initial adjudication by the Financial Ombudsman service in May 2003 found complainants had been given negligent and misleading advice. Equitable Life appealed and the ombudsman is now considering a final decision in the light of comments on a legal opinion on how to approach redress.

A key decision due in the last quarter of 2003 is the Financial Ombudsman’s ruling on five lead mis-selling cases dealing with people who bought policies between September 1998 and July 2000 when the house of Lords decision was announced.

**Equitable’s Reputation**

The Society had an enviable track record of offering a cost efficient service to its members. No commissions were paid to intermediaries and the administration capabilities were seen as amongst the best in the industry. As the Society did not pay commissions to intermediaries it is possible that very few intermediaries made any searching comparisons between the Society and its peers, and therefore the Society was able to adopt policies and practices which were not prevalent in the industry.
Equitable’s Bonus Philosophy

1.36 The Society is unique amongst mutual insurers in that it did not maintain a free reserve. The philosophy was that each generation of policyholders should get its own asset share and neither inherit from the past or give to the future. This stance led to higher bonus levels in periods of high investment returns and this helped the sales force generate high volumes of new business, and this subsequently led to low costs of administration.

Equitable’s Business Mix

1.37 The Society benefited from the legislation in the 1970’s that encouraged saving for retirement and the majority of the Society’s business relates to this type of business. Given its market positioning many of its members were self-employed and in the professions. As the contracts were designed to be flexible for the self-employed who tend to have variable earnings these contracts allow for variable premiums and therefore these policyholders have the open ended option to invest new premiums which benefit from the GAR. Approximately 25% of the assets are in respect of the GAR policyholders.

Industry Issues

1.38 Many intermediaries and insurance companies have had to pay compensation to policyholders because of alleged mis-selling of pensions contracts where individuals were encouraged to leave their occupational schemes even though this was not in the policyholder’s best interests.

Reasons:
- Concentrated in pensions business
- High proportion of contracts with open ended options
- Low level of surplus (in line with philosophy)
- Court’s view different to Directors
- No documented method of charging for guarantees and options (i.e. differential bonus policy from when contracts were introduced)
- Industry issues (pensions mis-selling)

F.1.4 Nissan Mutual Life (Japan)

Background:

1.39 The Ministry of Finance ordered suspension of business according to Insurance Business Law in April 1997. It was the first failure of insurance company in Japan after the World War II. Liabilities in excess of assets were Y322.2 billion.

Possible Reasons:
- single premium (or prepaid premium) annuity with too high guaranteed rates
- bad debt caused by loans to realty business
- high risk investment
- collapse of “bubble” economy (crash of stock, property and real estate markets)
- continuation of extraordinary low interest rate policy
- a large amount of negative interest rate spread
1.40 The Life Insurance Association of Japan established a new company, (i.e. Aoba Life Insurance Company), and transferred insurance contracts en bloc to the company. Then the guaranteed interest rate was lowered. Aoba Life received financial aid of Y200 billion from The Life Insurance Industry’s Fund for Policyholder Protection. In November 1999, Aoba Life was sold to a subsidiary company of Althemis, France. After this case, disclosure of solvency margin to the public became required.

F.1.5 Taisei Fire and Marine (Japan)
Background:
1.41 The Taisei Fire & Marine filed for protection under the special corporation rehabilitation law for insurers to the Tokyo District Court in November 2001 and their property was preserved intact. Liabilities in excess of assets were Y94.5 billion.

Possible Reasons:
- a large amount of reinsurance claims to be paid particularly including claims arising from the 11 September 2001 terrorist attacks in the United States
- reinsurance arrangement was entrusted to an agent in the U.S.
- reinsurance contract does not transfer the risk
- management does not grasp the risk of the reinsurance contract
- insufficient risk management

1.42 The Taisei is to merge with the Sompo Japan Insurance Inc.; the second largest general insurance company in Japan, in December 2002 after it sold off the reinsurance business. The Taisei received financial aid of Y5.3 billion from the Non-life Insurance Policyholders Protection Corporation of Japan.

F.1.6 Common Threads
1.43 It would be too simplistic to dismiss the similarities between the various case studies as being related to “out on a limb” decisions by key personnel not covered adequately by internal risk control practices.

1.44 Perhaps a more helpful analysis would be to identify the lack of key information as a means of precipitating the type of badly founded decisions that appear to have led to most, if not, all of our examples of company failure.
APPENDIX G  Introduction to Insurance Risk

G.1  Insurance Risk Example

1.1 The insurance business is difficult to assimilate for anyone not involved in its intricacies on a
day-to-day basis. Many aspects of the business are counter-intuitive, even to those well versed in
the broader commercial business markets.

1.2 The following example uses the analogy of the rolling of dice to help explain the uncertainty of
outcomes for all insurance contracts, and the rationale for the need for capital support that this
engenders for the business.

G.1.1 Insurance Basics

1.3 A number of features are common to all insurance transactions:

- Outcomes of risks from individual policies are unknown when underwritten
- However, when many similar risks are underwritten, expected results of total portfolio
  become more predictable
- Claims processes are driven by:
  - Frequency (or probability) of a claim event occurring; and
  - Severity (of size) of a claim if it occurs
- Risks inherent in different classes of insurance vary:
  - High frequency / low severity (e.g., motor and health) – outcomes easy to predict reliably
  - Low frequency / high severity (e.g., earthquake and hail) – outcomes hard to predict reliably

G.1.2 The Need for Capital

1.4 For an insurance company, capital is essentially needed to cover the risk of business outcomes
being greater than those predicted (i.e. largely the cost of claims to be settled in the future relating
to business already underwritten, but also assets being held to support those claims and the
relevant future operational costs).

- Premiums charged generally pay for expected losses (50% Probability) plus expenses of
  operation
- Insurers must have capital so as to be able to fund unexpected losses (when claims exceed
  expected levels)
- Profit margin in premium charged generally provides the return on capital needed when
  unexpected losses arise
- Provides support in face of adverse unexpected outcomes from insurance activities,
  investment performance and operations
- Finances growth and capital expenditure
- Provides security to policyholders that claims will be paid
- Can be defined as = Total Assets – Total Liabilities
G.1.3 Capital Management

1.5 There is a “healthy tension” between policyholders’ needs and shareholders’ (stakeholders’) needs that creates a balanced position when determining the appropriate capital support needs for the business.

The Balance of Capital:

- Policyholders and Supervisors will always like to see more capital
  - Better Security
  - Better Credit Ratings attract business
- Shareholders will generally like to see less capital
  - Enables better RoE
  - But less capital = higher risk

1.6 Here is a good point to introduce our example. It helps someone uninitiated in the intricacies of insurance contracts and risk management to understand how the “right” amount of capital is determined by a company’s Board and senior management.

G.1.4 The Unbiased Die Example

1.7 We shall use the random outcomes of throwing an unbiased die to illustrate the uncertainty of outcomes from insurance contracts, and how insurers deal with the risks to their business that this entails.

G.2 Reserving for Claims

Illustration

2.1 Assume we roll a unbiased die 100 times to represent the results of underwriting 100 policies
If 1 is result, insurer pays a claim of $1
If 2 is result, insurer pays a claim of $2
- etc.
- If 5 is result, insurer pays a claim of $5.

Illustration

2.2 What is the likelihood that total claims will be greater than $250?
2.3 The higher the amount reserved the greater the probability that there are sufficient funds to pay all claims.

Levels of Reserving - IBNR known as “incurred but not reported or claim amount (Before the Die is thrown)

<table>
<thead>
<tr>
<th>Probability of SUFFICIENCY PoS</th>
<th>Level</th>
<th>$ needed</th>
</tr>
</thead>
<tbody>
<tr>
<td>50%</td>
<td>Central estimate</td>
<td>$250</td>
</tr>
<tr>
<td>75%</td>
<td>Illustrative Supervisor’s Minimum Requirement</td>
<td>$262</td>
</tr>
<tr>
<td>90%</td>
<td>Illustrative Company Standard</td>
<td>$272</td>
</tr>
</tbody>
</table>
2.4 Hence, at outset we have a liability of $272

2.5 This amount is greater than the amount with which the Insurance Supervisor would see as an absolute minimum for safely managing the business, and consistent with the company’s view of the “appropriate appetite for risk”.

G.3 Premium and Profit

3.1 Retaining our “die” example, we now illustrate the concepts of premium and profit by introducing a cost for each of our 100 throws.

Illustration - Premium & Profit

3.2 For simplicity, assume there are no expenses. Suppose insurer charges $3 per throw. Hence total premium = $300 “Expected” profit = $300 - $250 = $50 (A lower profit will occur 50% of the time and higher profit will occur 50% of the time)

Is this the profit that can be reported as earned?

Levels of Reserving
(After 50 throws)

Suppose after 50 throws we have:

<table>
<thead>
<tr>
<th>RESULT</th>
<th>FREQUENCY</th>
<th>CLAIMS $</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>7</td>
<td>7</td>
</tr>
<tr>
<td>2</td>
<td>7</td>
<td>14</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>21</td>
</tr>
<tr>
<td>4</td>
<td>7</td>
<td>28</td>
</tr>
<tr>
<td>5</td>
<td>7</td>
<td>35</td>
</tr>
<tr>
<td>6</td>
<td>15</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>50</td>
<td>105</td>
</tr>
</tbody>
</table>

3.3 Reserve will now be = Actual Claims + IBNR for remaining 50 throws = 105 + 272 x 50 / 100 = 241

“IBNR” stands for “Incurred but not Reported” and reflects the unknown outcome of claims relating to policies (or throws of the die) for which we have already received a “premium”. 
Profit Reported

3.4 Premium = $300
Actual claims are $105 compared $125 expected
Hence profit after first 50 throws
= $300 – (105 + 272/2)
= $59
This profit has three components
25 Expected Profit ( (300 - 250)/2 )
20 “Unexpected” Profit (125-105)
14 Release of Risk Margin (50% of (300 - 272) )
59

3.5 So we have demonstrably done better than expected. No uncertainty remains about the outcomes of the 50 throws we have made, so we can safely recognise the profit relating to those throws broken down into the three types in the above table.

Levels of Reserving
(After 100 throws)

3.6 Suppose after 100 throws we have:

<table>
<thead>
<tr>
<th>RESULT</th>
<th>FREQUENCY</th>
<th>CLAIMS $</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10</td>
<td>10</td>
</tr>
<tr>
<td>2</td>
<td>10</td>
<td>20</td>
</tr>
<tr>
<td>3</td>
<td>20</td>
<td>60</td>
</tr>
<tr>
<td>4</td>
<td>20</td>
<td>80</td>
</tr>
<tr>
<td>5</td>
<td>18</td>
<td>90</td>
</tr>
<tr>
<td>6</td>
<td>22</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>100</td>
<td>260</td>
</tr>
</tbody>
</table>

3.7 Reserve will now be = Actual Claims
= $260

Levels of Reserving

3.8 Premium earned for 100 throws = $300
Actual claims are $260 compared to $250 expected
Hence profit from 100 throws
= $300 - 260
= $40
Profit/(loss) from 100 throws was
50 Expected Profit
(10) “Unexpected” Loss (250-260)
40
3.9 Note that the result of the second 50 throws was a loss of 19 as 
40 - 59 = ( 19 )

3.10 So, because we have presumably already used the profit from the first 50 throws, we must now 
draw on our capital to support the loss from the second 50 throws. (If we were being prudent, of 
course, some of our profit from the first 50 throws may have bolstered our capital).

G.4 Capital Requirement

4.1 Even if we were being prudent, we could not guarantee that we would be solvent after either the 
first 50 or first 100 throws, or whenever unless we had an extra “cushion” of capital to support 
our business. (What if the second 50 throws had come first? What if we had the same outcome for 
the second 50 throws for all of the 100 throws?)

4.2 Assume that the Minimum Capital Requirement (MCR) the Supervisor requires in addition to the 
outstanding claims liability in this case is $100.

4.3 Hence possible range of funds insurer needs at outset is:

<table>
<thead>
<tr>
<th>PoS</th>
<th>Liability</th>
<th>MCR</th>
<th>Total Funds Needed</th>
</tr>
</thead>
<tbody>
<tr>
<td>75%</td>
<td>262</td>
<td>100</td>
<td>362</td>
</tr>
<tr>
<td>90%</td>
<td>272</td>
<td>100</td>
<td>372</td>
</tr>
</tbody>
</table>

Illustration - Capital Needed

4.4 What capital does insurer need to have in addition to the premium charged to be able to operate?

<table>
<thead>
<tr>
<th>PoS</th>
<th>Total Funds</th>
<th>Premium Needed</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>362</td>
<td>62</td>
</tr>
<tr>
<td></td>
<td>372</td>
<td>72</td>
</tr>
</tbody>
</table>

4.5 Note that this reflects the minimum capital support position.

Illustration Profit (Loss) & Returns on capital (RoC)

<table>
<thead>
<tr>
<th>PoS</th>
<th>CAPITAL LEVEL</th>
<th>WORST RESULT</th>
<th>BEST RESULT</th>
<th>EXPECTED RESULT</th>
<th>EXPECTED RoC</th>
</tr>
</thead>
<tbody>
<tr>
<td>75%</td>
<td>62</td>
<td>(200)</td>
<td>300</td>
<td>50</td>
<td>80% = 50/62</td>
</tr>
<tr>
<td>90%</td>
<td>72</td>
<td>(200)</td>
<td>300</td>
<td>50</td>
<td>69% = 50/72</td>
</tr>
</tbody>
</table>

Illustration Risk of Ruin

4.6 But what is wrong with these scenarios? If claims exceed $372 the insurer will fail! Hence, the 
insurer needs reinsurance to prevent this outcome.

4.7 “Hence the insurer probably needs more capital, since the likelihood of failure will appear too 
great to a prudent Board of Directors. An alternative that may appear more efficient is the use of 
reinsurance. We shall extend our example to include an illustration of the value of reinsurance in 
reducing the risk to the insurer”
G.5 Reinsurance

5.1 Illustration - Reinsurance

- If claims exceed $362 an insurer operating at 75% PoS will be bankrupt ($372 for 90% PoS).
- The Supervisor will want safeguards in place to prevent this, so reinsurance must be purchased.
- If reinsurer agrees to pay all claims in excess of $362 for a cost of $38, or all claims over $372 for $36, what is the result?

Illustration - Reinsurance Impact

<table>
<thead>
<tr>
<th>PoS</th>
<th>CAPITAL LEVEL</th>
<th>EXPECTED PROFIT BEFORE REINSURANCE</th>
<th>REINSURANCE COST</th>
<th>EXPECTED PROFIT AFTER REINSURANCE</th>
<th>EXPECTED RoC</th>
</tr>
</thead>
<tbody>
<tr>
<td>75%</td>
<td>62</td>
<td>50</td>
<td>38</td>
<td>12</td>
<td>19%</td>
</tr>
<tr>
<td>90%</td>
<td>72</td>
<td>50</td>
<td>36</td>
<td>14</td>
<td>19%</td>
</tr>
</tbody>
</table>

5.2 It will be noted that the return on capital is now much lower than in our “un-reinsured” illustration. However, it is still better than the return would have been if we had increased the capital support to the substantially increased level that would have effectively nullified the risk of failure (without the reinsurance).

G.6 Summary

6.1 This simple example shows that,
- Reserving Levels
- Capital Requirements
- Premiums Charged
- Projected Profit
- Expected Return on Capital; and
- Reinsurance needs
- All are INTERLINKED in their impact on an insurer’s overall financial position.

6.2 The example also demonstrates how the risks inherent in insurance business create a distinctive set of management decisions related to the balance between risk and return on invested capital.
APPENDIX H  Analytic Methods

H.1  Developing a Base-Line Model

1.1  This Appendix deals initially with analytic methods for developing the base-line model, the multivariate Normal distribution, as well as risk measure. It then goes on to deal with non-Normal risks for which analytic approximations to risk measures are developed. These are used for developing factor-based formulas that are good approximations to results using an internal model.

1.2  Since, for internal models, the distribution of the outcome $X$ may be quite complicated, it is useful to develop a “base-line” model of the distribution of the outcome, recognizing that approximations are involved. The cumulant generating function of $X$ is

$$
\varphi_X(t) = \ln E(e^{tX}).
$$

1.3  The cumulant generating function for each distribution is unique and characterizes the distribution. It can be written as a series expansion as

$$
\varphi_X(t) = \mu t + \sigma^2 \frac{t^2}{2} + \kappa_3 \frac{t^3}{3!} + \kappa_4 \frac{t^4}{4!} + \cdots
$$

1.4  Where $\mu$ is the mean of the distribution, $\sigma^2$ is its variance and $\kappa_3, \kappa_4, \cdots$ are the higher cumulants of the distribution. The Normal distribution has cumulant generating function

$$
\varphi_X(t) = \mu t + \sigma^2 \frac{t^2}{2}
$$

1.5  With all higher cumulants equal to zero. Hence, the Normal distribution can be viewed as a first-order approximation to the “true” distribution.

1.6  Applying this idea to all the risk components, as well as at to the aggregate risk, results in the multivariate Normal distribution serving as the first-order approximation or base-line model.

1.7  The error of the approximation can be measured by examining the size of the higher cumulants or by other methods. One such method is to obtain upper bounds on the error of key quantities such as risk measures when the mean and variance are fixed but the higher cumulants are unknown. There is well-developed theory for finding these upper bounds. It is not anticipated that such bound would be used in practice. However, they are useful for a supervisor in evaluating the maximum possible error in adopting a relatively simple model as a baseline model.

1.8  If $X_1, X_2, \ldots, X_n$ have a multivariate Normal distribution (or the Normal model is used as a first approximation), the model is completely specified by its mean vector and its covariance matrix:

$$
\begin{pmatrix}
\sigma_1^2 & \rho_{12}\sigma_1\sigma_2 & \cdots & \rho_{1n}\sigma_1\sigma_n \\
\rho_{12}\sigma_1\sigma_2 & \sigma_2^2 & \cdots & \rho_{2n}\sigma_2\sigma_n \\
\vdots & \vdots & \ddots & \vdots \\
\rho_{1n}\sigma_1\sigma_n & \rho_{2n}\sigma_2\sigma_n & \cdots & \sigma_n^2
\end{pmatrix},
$$
1.9  Where $\rho_{i,j}$ is the correlation between the $i$-th and the $j$-th risk components, and $\sigma_j$ is the standard deviation of the $j$-th component.

1.10  The standard deviation of the aggregate distribution is $\sigma = \sqrt{\sum_{i,j=1}^{n} \rho_{i,j} \sigma_i \sigma_j}$.

1.11  Thus, within the Normal distribution framework, by specifying the correlations of all pairs of component risks and the means and standard deviations of each, the aggregate distribution can be fully specified.

1.12  In practice, two major sources of error need to be recognized. First, when the Normal model is used as a base-line model, the “true” distribution, errors can occur. The true probability distributions associated with particular risks may be quite different from the Normal distribution. Although the Normal distribution is used extensively in financial theory, it is often found the observed extreme events suggest a tail of the distribution that is heavier than that of the Normal distribution. Heavier tails are also observed for losses for many insurance lines, especially in the property-liability areas. Typical risk measures, such as standard deviation or VaR can seriously underestimate the true risk the true model is significantly different from the Normal distribution. Second, when the marginal distributions of the various risks are combined into a multivariate distribution, the linear correlation used in the Normal distribution may not be well suited to combining interactions in the extreme tails of the distribution, since normal correlation describes the degree of linearity of the relationship between two risks over the entire range of the distributions, and does not focus mainly on the tails, which is the area of interest for supervisors.

1.13  A supervisory framework can recognize the errors described in the previous paragraph in a number of ways:

   a)  Requiring a multiple (e.g. 150%) of the capital indicated by using a specific model. This provides a cushion for “model error.”

   b)  Incorporating directly some conservative elements into assumptions, parameters, and correlations in the base-line model.

H.2  Base-Line Capital Requirement Framework

2.1  The base-line risk measure “standard deviation” is closely related to other concepts in the case of normally distributed risks. One such concept is the Value-at-Risk (VaR) that corresponds to a quantile that is away from the mean by a fixed multiple of the standard deviations. For instance, the 99\textsuperscript{th} percentile corresponds to 2.33 times standard deviation in addition to the mean as a total balance sheet requirement.

2.2  When the standard deviation is used as the risk measure and the indicated capital requirement is a multiple of the standard deviation

$$C_j = k\sigma_j,$$
2.3 The capital requirement of the aggregate risk can be written as

\[ C = \sqrt{\sum_{i,j=1}^{n} \rho_{ij} C_i C_j}. \]

2.4 This formula provides a base-line formula capital requirement. It requires calculation of the indicated capital requirement for each component risk and combining them using the above formula which incorporates the linear correlation coefficient as a measure of association between the component risks. It is noteworthy that for the Normal distribution, the above formula also holds if TailVaR is used as a risk in place of standard deviation.

2.5 In practice, insurance risks and investment risks often depart from the multivariate Normal assumptions, and the baseline risk-measures become less effective. Common criticisms of risk measures based on the Normal distribution include:

a. they may fail to differentiate between upside and downside for risks with skewed and fat-tailed distributions;

b. they may fail to reflect non-linear correlations (e.g. higher tail correlations); and

c. they may violate some of the “consistency” rules for a coherent risk measure.\(^{20}\)

2.6 To address some of these issues, there have developed analytic tools that can overcome the drawbacks of the baseline risk measures for non-Normal distributions, while still retaining the baseline for Normally distributed risks.

2.7 An example of one such coherent risk measure that extends the standard deviation for non-Normal risks is the Wang Transform. For a risk with a loss distribution \(F(x)\), the Wang transform \(F^*(x) = \Phi[\Phi^{-1}(F(x)) - \lambda]\) gives a transformed distribution, where \(\Phi\) is the standard normal cumulative distribution function. The Wang transform of a Normal distribution with mean \(\mu\) and standard deviation (volatility) \(\sigma\) is another Normal distribution but with the mean replaced by \(\mu + \lambda \sigma\) and the standard deviation, \(\sigma\), unchanged. In this case, the mean of the transformed distribution \(\mu + \lambda \sigma\) is the risk measure, or required capital.

H.3 Analytic Approximations

3.1 In order to develop factor-based formulas for capital requirements that reflect the individual characteristics of an insurance company, one needs to develop “exposure” quantities, measuring the level of risk-exposure of the company to any risk type. Thus, one can consider the capital \(C\) as a function of the exposure levels of each of the component risks. In practice these exposure measures need to be defined. Simple proxies for exposures can include amounts-at-risk, premiums, or reserves, among others.

3.2 Thus one can write

\[ C(e_1, e_2, \ldots) = \int x \cdot dg[F(x)] \]

where \(e_j\) is the exposure measure for the \(j\)-th risk component. Note that we can rewrite the loss as

\[ X_j = e_j \cdot Y_j \]

---

\(^{20}\) See Artzner, Ph 1991 Application of coherent risk measures to capital requirements in insurance. NAAJ 3, Nov 2,11-25t
where \( Y_j \) is a new standardized loss variable.

\[
C(\lambda e_1, \lambda e_2, \ldots) = \lambda C(e_1, e_2, \ldots).
\]

3.3 This is not generally true. It is true for some types of risks but the basis of insurance is LLN, where the very idea is that the homogeneity property is NOT satisfied (e.g. if the amounts at risk in fire insurance increase due to increase in the number of policies). The expression above should be modified accordingly. Consequently, all subsequent considerations (except as approximations) hold only for cases, where homogeneity property is satisfied.

3.4 This is easily justified by considering a change of currency. From this, it follows that

\[
\sum_j \frac{\partial C}{\partial e_j} \cdot e_j = C.
\]

H.4 Linear Approximation

4.1 One can then write a simple series expansion for the capital function \( C \). For a specific company in terms of the capital function for a base-line representative company with exposures \( e_1^0, e_2^0, \ldots \). The mix of risks of the base-line representative company will be referred to as the target point or target mix.

4.2 In practice most capital functions will be highly non-linear functions of the exposure variables and will likely exist as complex computer models rather than closed form analytic expressions. Since the capital function may be difficult and expensive to compute, it makes sense to have analytic expressions which approximate the capital in a neighbourhood of a target point \( e_1^0, e_2^0, \ldots \). A simple Taylor expansion about this point yields

\[
C(e_1, e_2, \ldots, e_n) = C(e_1^0, e_2^0, \ldots) + \sum_j \frac{\partial C}{\partial e_j^0} \cdot (e_j - e_j^0) + \text{second order terms}.
\]

4.3 However, the homogeneity of the capital results in

\[
C(e_1, e_2, \ldots) = \sum_j \frac{\partial C}{\partial e_j^0} \cdot e_j + \text{second order \& higher order terms}.
\]

4.4 This means that if the actual mix of risks is close enough to the representative mix, the capital requirement is approximated by a factor-based formula where the factors are derived from the derivatives of the capital function at the target risk mix. Note that the factors depend on the mix of risks but not the scale of the risks at the target point.
5.1 If the linear approximation described above is not good enough it is possible to develop a convenient quadratic approximation to $C^2$. If we define the matrix $r_{i,j}$ at the target risk mix by

$$r_{i,j} = \frac{1}{2} \frac{\partial^2 C^2}{\partial e_i^o \partial e_j^o}$$

then a Taylor expansion of the function of $C^2$ shows that

$$C^2(e_1, e_2, ..., e_n) = \sum_{i,j} r_{i,j} e_i e_j + \text{third & higher order terms.}$$

5.3 This result clearly shows that, the approximation $C = \sqrt{\sum_{i,j} r_{i,j} e_i e_j}$ should be valid in a neighbourhood of the target risk mix. This is in the same spirit as the base-line capital formula suggested above.

5.4 A paper\textsuperscript{21} shows that for a standard deviation or TVaR risk measure on multivariate Normal risks the quadratic approximation is exact. In this case the $r_{i,j}$ terms are the linear correlation coefficients.

6.1 The approximation process generalizes to arbitrary $m$ in the sense that if we look at a Taylor expansion of $C^m$ we find that the first $m$ terms of the expansion collapse down to an expression of the form

$$C^m(e_1, e_2, ..., e_n) = \frac{1}{m!} \sum_{i_1, ..., i_m} \frac{\partial^m C^m}{\partial e_{i_1}^0 \partial e_{i_2}^0 \partial e_{i_m}^0} e_{i_1} e_{i_2} ... e_{i_m} + \text{terms of order } m+1 \& \text{higher.}$$

7.1 The methods described in the last section show how the base-line approximation can be improved. The base-line approximation is based on multivariate Normal distribution using standard deviation or TVaR as a risk measure. The results of quadratic approximation above allow for any risk measure and any distribution. One needs to obtain the second order derivatives of the square of the capital requirement $C$ for the representative company yielding the generalizations of the linear correlations. Once this is done for the industry, the calculations for each company are analogous to those under the base-line approximation.

7.2 Clearly, higher order approximation is also possible. However, at this point it is not known how much gain there will be in going beyond quadratic approximation.

\textsuperscript{21} H. Panjer, “Measurement of risk, solvency requirements and allocation of capital within financial conglomerates” Institute of Insurance and Pension Research, University of Waterloo, 2002.
Appendix I  Copulas

I.1  Introduction

1.1  Suppose that the overall risk $X$ of the company can be described as, $X = \sum_{j=1}^{n} X_j$ (i.e., $X$ can be decomposed into risk components $X_j$).

1.2  In the sequel, we assume that we can have adequate information and can describe the risks (i.e., we have models for the individual risks or risk components $X_j$). We now need to address the issue of combining these risks in order to obtain an appropriate model for $X$.

1.3  The model for $X$ is completely specified if we assume a multivariate Normal setting in which each component has a univariate normal distribution and all dependencies are expressed through correlations. However, insurance claim data immediately show shortcomings of this assumption as,
   • loss distributions are usually skewed and heavy tailed (i.e., the downside risk due to large losses is substantial,
   • dependency between risks usually increases in the tails (i.e., various lines of business may look almost independent in “normal” situations, but they are strongly correlated in the tails – as occurred with September 11, 2001).

1.4  Notice that in a multivariate Normal setting, the $X_j$’s are asymptotically independent if the linear correlations are less than one$^{22}$. Therefore, it is advisable to model dependencies in the above setting in a different way. To this end, copulas provide one feasible framework.$^{23}$

1.5  The following paragraphs briefly provide a mathematical overview, which is also given in more detail in Appendix H. More importantly, we describe in this Appendix more intuitively how copulas work and why they are an alternative approach to describing dependencies.

1.6  An $n$-dimensional copula is an $n$-dimensional distribution function with uniform marginal distributions. The dependence structure between $X_1, \ldots, X_n$ is described by $C$ if the distribution function $F$ of $X_1, \ldots, X_n$ is given by
   \[ F(x_1, \ldots, x_n) = C(F_1(x_1), \ldots, F_n(x_n)) \]
   where $F_j$ denotes the marginal distribution function of $X_j$. In other words, the joint distribution of the quantiles of $X_1, \ldots, X_n$ is given by the function $C$.

---

$^{23}$ For a comprehensive introduction and discussions of copulas, we refer to the papers Embrechts et al (op cit) and P. Embrechts, A. McNeil, D. Straumann, *Correlation and Dependence in Risk Management: Properties and Pitfalls*, RiskLab Research papers, Dept. Math. ETH Zürich, Aug. 1999, www.risklab.ch/Papers.html#Pitfalls which also serve as the main references for this section.
1.7 To illustrate the concept of copulas, four graphs have been prepared. Graph I.1 shows an example of two random variables $X_1, X_2$ which each have a marginal uniform distribution. The simulated joint samples are scattered across the plot showing no pattern and thus the outcome of the one variable seems to have no connection to the outcome of the other variable. In this case, the two variables are mutually independent.

**Graph I.1: Scatterplot of Two Independent Variables**

1.8 The other extreme of the joint outcome of two uniform variables would be that the outcome of $X_1$ predetermines the outcome of $X_2$. For example in Graph I.2, $X_1 = X_2$. In this case, the two random variables exhibit complete dependency.

**Graph I.2: Scatterplot of Two Perfectly Correlated Variables**
1.9 Finally, the most interesting case and more typical situation is when there is some dependency between the variables. The outcome of the two variables may appear at first glance to be uncorrelated. This is illustrated in Graph I.3. It would appear that the outcomes are approximately uniformly distributed over the square. However, on close examination of the more extreme cases where both variables are close to 1 or both are close to 0, the outcomes appear to be more dense (i.e., more clustered). This suggests that if $X_1$ is close to 1, it implies that $X_2$ is also more likely to be close to close to 1 as well.

**Graph I.3: Scatterplot of Two Variables That Exhibit Correlation in Both Tails**
1.10 Graph I.4 shows the application of a copula to two risks $X_1, X_2$ that are more representative of real data than Graph I.3. In this graph the axes are now in terms of real monetary values.

**Graph I.4: Scatterplot of Outcomes of Two Lines of Insurance.**

![Scatterplot of Outcomes of Two Lines of Insurance]

1.11 It can be seen from Graph I.4 that the nature of dependency between the two risks is different for smaller outcomes (as depicted in the lower left region) from that for large outcomes (as depicted in the upper right). In fact, the interdependency of the two risks when one of the outcomes is small is relatively low. However, when the outcome of one of the variables becomes larger, the other is more likely to also be larger, indicating an increasing co-movement. This example therefore shows clearly that the two risks have a dependency in the right-hand tail.

1.12 More technical background on copulas is given in subsequent sections of this appendix and in the references already cited.

I.2 Theoretical Background

2.1 In order to capture stochastic dependencies between insurance risks, the traditional concept of linear correlation is insufficient. In this technical appendix we introduce some of the mathematical framework of copulas which can be used to model dependencies on a deeper level. In this way, one can for instance take into account that many insurance risks seem to be almost independent in "normal" situations but heavily dependent in the extreme.

2.2 A copula is a function that associates the quantiles of one random variable to the quantiles of another random variable.
2.3 **Definition:** A $n$-dimensional copula is a distribution function $C:[0,1]^n \rightarrow [0,1]$ with uniform marginal distributions. The dependence structure between $X_1,\ldots,X_n$ is described by $C$ if the distribution function $F$ of $X_1,\ldots,X_n$ is given by

$$F(x_1,\ldots,x_n) = C(F_1(x_1),\ldots,F_n(x_n))$$

where $F_j$ denotes the marginal distribution function of $X_j$. In other words, the joint distribution of the quantiles of $X_1,\ldots,X_n$ is given by $C$.

2.4 Suppose now that the dependence between $X_1,\ldots,X_n$ can be described by a copula $C$ and that each $X_j$ can be adequately represented by a model (i.e., we know the marginal distribution functions $F_j$). Furthermore, we assume that we have an algorithm to simulate independent random vectors $(u_1^k,\ldots,u_n^k)$, $k=1,2,\ldots$ from $C$. Then $F_1^{-1}(u_1^k) + \cdots + F_n^{-1}(u_n^k)$ are independent random samples of $X$ and in this way we have obtained a model for $X$.

2.5 **Definition:** The *upper* and *lower tail dependence* between two random variables is respectively

$$\lambda_u(X_1,X_2) = \limsup_{u \downarrow 1} P(X_1 > F_1^{-1}(u) \mid X_2 > F_2^{-1}(u))$$

and

$$\lambda_L(X_1,X_2) = \limsup_{u \downarrow 0} P(X_1 \leq F_1^{-1}(u) \mid X_2 \leq F_2^{-1}(u)),$$

2.6 The tail dependencies can be determined *directly* from the copula for $X_1$ and $X_2$.

2.7 Since copulas describe the dependence between variables on the level of quantiles, the following property holds:

2.8 **Property:** Suppose that $C$ is a copula for $X_1,\ldots,X_n$. If $\varphi_1,\ldots,\varphi_n$ are non-decreasing functions, then $C$ is also a copula for $\varphi_1(X_1),\ldots,\varphi_n(X_n)$.

2.9 This property has the following practical applications:

- Insurances, government agencies, brokers etc have access to sensitive claims data which they do not want to or may not be allowed to make public use of. However, after transforming the data by an increasing function, the data is not back traceable, i.e. has lost substantial sensitivity, but it contains still the same information for estimating copulas. Copulas are thus a potential tool to make otherwise sensitive data available to public use with out violating confidentiality.

- A reinsurance structure in a certain line of business typically is a non-decreasing function of the underlying losses. Hence, the copula for the gross losses can reliably be assumed to be the same for the net losses.
I.3 Some Parameterised Families of Copulas

Gauss Copulas

3.1 Let \( \Phi \) denote the distribution function of the standard normal distribution and \( \Phi^x \) the \( n \)-variate standard normal distribution function with correlation matrix \( R \). The \( n \)-dimensional Gaussian copula with correlation matrix \( R \) is given by
\[
C^\text{Gauss}_R(u_1, \ldots, u_n) = \Phi_R(\Phi^{-1}(u_1), \ldots, \Phi^{-1}(u_n)).
\]

3.2 If \( X_1, \ldots, X_n \) are multivariate normally distributed with correlation matrix \( R \), then their copula is \( C^\text{Gauss}_R \).

3.3 It is important to note that Gauss copulas are not suitable to model the tail of \( X \). Indeed, if the correlation \( R_{ij} \neq 1 \), then the tail dependencies between \( X_i \) and \( X_j \) are zero\(^{24}\).

T-Copula

3.4 In order to overcome this shortcoming of Gaussian copulas, t-copulas could be used. In the same way as the Gaussian copulas, they are parameterized by a “correlation matrix” but there is one additional parameter to control the tail dependencies. The limiting case \( \nu = \infty \) is the corresponding Gaussian copula.

3.5 Suppose \( Y_1, \ldots, Y_n \) are multivariate normally distributed with correlation matrix \( R \) and \( S \) is a random variable with \( \chi^2_{\nu} \)-distribution. Let \( t_{\nu,R}^n \) denote the distribution function of \( \sqrt{\nu/S} \cdot (Y_1, \ldots, Y_n) \) and \( t_{\nu,R} \), the distribution function of \( \sqrt{\nu/S} \cdot Y_i \), i.e., the equal margins of \( t_{\nu,R}^n \).

Then the t-copula with parameters \( \nu, R \) is given by
\[
C_{\nu,R}(u_1, \ldots, u_n) = C_{\nu,R}^t(t_{\nu,R}^{-1}(u_1), \ldots, t_{\nu,R}^{-1}(u_n))
\]

3.6 The tail dependencies for the copula \( C_{\nu,R} \) are
\[
\lambda_\nu(X_i, X_j) = \lambda_\nu(X_j, X_i) = 2 - 2t_{\nu+1}(\sqrt{\nu+1}/\sqrt{1-R_{ij}}).\]

3.7 In order to aggregate models for \( X_1, \ldots, X_n \) with a t-copula, we need an algorithm to generate independent samples \( (u_1, \ldots, u_n) \) of \( t_{\nu,R}^n \). A feasible algorithm is:
- Find the Cholesky decomposition \( A \) of \( R \).
- Simulate \( n \) independent random numbers \( z_1, \ldots, z_n \) from the standard normal distribution.
- Simulate a random number \( s \) from \( \chi^2_{\nu} \) independent of \( z_1, \ldots, z_n \).
- Set \( x = \sqrt{\nu/S} \cdot Az \).
- Set \( u_j = t_{\nu}(x_j), \ j = 1, \ldots, n \).

---

3.8 This algorithm to generate random samples of the t-copula is fast.

**Coomonotonic Copula:**

3.9 The coomonotonic copula ensures that risks always move in the same direction. This is a kind of “worst case” for insurers. As such, the results provide an upper bound on the capital requirement since quantiles (VaR) and TailVaR risk measures are additive. In the special case of the multivariate Normal distribution, the results correspond to assuming a correlation of 1 between risks.

3.10 In general, any dependency at a single point in the multivariate distribution can be described as a linear combination of the coomonotonic copula and the independent copula (obtained by multiplying marginal distributions together).
Glossary

Coefficient of variation: The ratio of the standard deviation to the mean of a distribution.

Coherent: A risk measure satisfying the following four axioms is called coherent (note that other risk measures not satisfying one or more of these axioms may have useful properties as well).
- Subadditivity - Capital for two risks is not larger than sum of capital for each risk separately.
- Positive homogeneity - Capital is invariant under scale transformations (doubling the risk doubles the capital).
- Translation invariance - Capital is invariant under location transformations (adding a certain risk increases the capital with this certain amount).
- Monotonicity - Capital is larger for larger risks.

Comonotonic: Two random variables, X and Y, are said to be comonotonic if there exists another variable, Z, and increasing real-valued functions, u and v, such that \( X = u(Z), Y = v(Z) \). When the outcomes of insurers A and B are comonotonic; that is, they always move up or down together, then it is believed that the required capital for the combined company should equal the sum of the required capitals for the two individual companies.

Copula: A copula is a function that associates the distribution function of one random variable to the distribution function of another random variable. Using copulas to model dependencies on a deeper level, one can for instance take into account that many insurance risks seem to be almost independent in "normal" situations but heavily dependent in the extreme.

Credit risk: Credit risk is the risk of default and change in the credit quality of issuers of securities, counter-parties and intermediaries, to whom the company has an exposure.

Diversifiable risk: A risk is diversifiable when the volatility of the average claim amount declines as the block of combined insurer risks increases.

Economic capital: Economic capital is what the firm judges it requires for ongoing operations and, for an insurance company, what it must hold in order to gain the necessary confidence of the marketplace, its policyholders, its investors and its supervisors.

Liquidity risk: Liquidity risk is exposure to loss in the event that insufficient liquid assets will be available, from among the assets supporting the policy obligations, to meet the cash flow requirements of the policyholder obligations when they are due or assets may be available, but only at excessive cost.

Market risk: Market risk arises from the level or volatility of market prices of assets. Market risk involves the following:
- exposure to movements in the level of financial variables
- exposure of options to movements in the underlying asset price
- exposure to other unanticipated movements in financial variables
- exposure to movements in the actual or implied volatility of asset prices and options

Non-diversifiable risk: A risk is non-diversifiable when it cannot be (relatively) reduced by increasing portfolio size.
Operational risk is defined as the risk of loss resulting from inadequate or failed internal processes, people, systems or from external events.

A $\alpha$-quantile of a random variable $X$ is any value $x$ such that $\Pr(X \leq x) = \alpha$. For example, the 95$^{th}$ percentile of the distribution is the value for which there is a probability of exceedence of 5%. Value-at-Risk (VaR) is a quantile of the distribution.

Risk is the chance of something happening that will have an impact upon objectives. It is measured in terms of consequences and likelihood.

Also called non-diversifiable risk

Tail-Value-at-Risk (TVaR or TailVaR) is the quantile VaR plus the average exceedence of that quantile if such exceedence occurs. Alternatively, TVaR at level $p$ is the arithmetic average of all VaR’s from level $p$ on. It is sometimes also called Conditional Tail Expectation (CTE) or Expected Shortfall.

Time horizon is a period over which a risk is measured. Assuming a certain fixed acceptable level of insolvency risk per year, extending the time horizon should always result in a higher capital need.

Total balance sheet requirement is the sum of both the liabilities and solvency capital requirement upon realistic values. Using the total balance sheet requirement allows solvency assessment to be relatively independent of the accounting system.

Type A credit risk is the credit risk relating to actual assets held.

Type A market risk is the market risk relating to the volatility of the market value of the actual assets held and the market value of the replicating portfolio of assets.

Type B credit risk is the credit risk involved with future reinvested assets.

Type B market risk is the market risk involved with future reinvestment assets and long term options and/or guarantees.

Underwriting is the specific insurance risk arising from the underwriting of insurance contracts. The risks within the underwriting risk category are associated with both the perils covered by the specific line of insurance and with the specific processes associated with the conduct of the insurance business.

Volatility is the risk of random fluctuations in either the frequency or severity of a contingent event.
Exposure Draft of the Proposed International Actuarial Note (IAN) 100 on Application of IFRS 17 Insurance Contracts

Attached (below) is an exposure draft (ED) of the International Actuarial Note (IAN) on Application of IFRS 17 Insurance Contracts. The ED has been drafted by the Education and Practice (E&P) Subcommittee of the Insurance Accounting Committee (IAC) of the International Actuarial Association (IAA). The IAN is educational, and is not intended to be authoritative.

We ask you to distribute this consultation document (also available under Publications / IANs on the IAA website) widely within your organization and to any other interested parties in your jurisdiction.

The official deadline for comments is 26 April 2019.

The preferred format for submitting comments is the comment template attached to the transmittal e-mail. If a mark-up of the ED is also submitted, we recommend using the comment feature liberally, giving reasons for proposing the change. Comments should be addressed to IAN100.comments@actuaries.org with IAN100 in the email header. Each comment should make it clear if it is a personal response or one representing a particular organization, standard-setter or other entity.

All comments will normally be posted to the IAA website identifying the commentators. However, in exceptional cases, in response to a request which the IAA Secretariat is satisfied is for a valid reason, comments may either be posted to the website anonymously or withheld from the website.

We ask for commentators particularly to consider the following questions:

1. Is the IAN clear and unambiguous? If not, how should it be changed?
2. Is the IAN sufficient and appropriate in dealing with the Chapter headings? If not, how should it be changed?
3. Is the IAN at the right level of detail? If not, how should it be changed?
4. Where guidance is still ambivalent (awaiting further interpretation of IFRS 17) is there preferred guidance?
5. Are there any other matters that should be included in this IAN?

We would encourage readers to perform a critical review of the exposure draft. IFRS 17 is a very complex document, and different interpretations are possible for certain items. The exposure draft attempts to discuss these varying interpretations in several places, but more subjects for this ambiguity may exist than are currently identified in this draft. We also ask reviewers to suggest topics and situations seen in multiple jurisdictions in applying IFRS 17 that the IAN may have overlooked, or where reviewers disagree with the IAN’s current description of an item.

Thank you in advance for your attention to this matter. The E&P and IAC look forward to the responses.

The E&P Subcommittee recognizes that, in many cases, member associations will be drafting their own detailed educational notes on IFRS 17. The intention of the attached IAN 100 is that it dovetails with such jurisdictional educational notes in giving comprehensive educational reference for actuaries working on the provision of support to work on accounts being prepared under IFRS 17.
Exposure draft of IAN 100

International Actuarial Note 100
Application of IFRS 17 Insurance Contracts

17 January 2019

This International Actuarial Note is an educational document. It serves to familiarize actuaries with approaches that might be taken to work relating to IFRS 17 Insurance Contracts and to demonstrate how the actuarial profession might approach the topic. It does not impose any obligation on any IAA Member Association or any individual actuary to promote or apply the practices described. It is not a definitive statement as to what constitutes generally accepted practice in the area under discussion and the language used is not directive.
An International Actuarial Note (IAN) is an educational document that provides information on current or emerging practices in relation to an international actuarial topic. It serves to familiarize actuaries with approaches that might be taken and to demonstrate how the actuarial profession might approach the topic. The major difference between an IAN and other IAA educational documents is that all IAA Member Associations must be invited to provide input to the IAN through a formal consultation process, which maximises the capacity to identify any material differences of opinion on the content of the IAN.

An IAN does not impose any obligation on any IAA Member Association or any individual actuary to promote or apply the practices described. It is not a definitive statement as to what constitutes generally accepted practice in the area under discussion and the language used is not directive.

An IAN may address a topic that is also addressed by an International Standard of Actuarial Practice (ISAP) issued by the IAA. In that case, the IAN will not conflict with the ISAP. The IAN does not seek to interpret the ISAP and it is not intended as a description of how an IAA Member Association might interpret the ISAP. Nor is it intended as a description of how an actuary might apply the ISAP or any actuarial standard based on the ISAP, though it might assist in that regard.

INTRODUCTION

This IAN has been written to assist actuaries in complying with IFRS17 and ISAP 4, by offering practical examples of ways in which actuaries might implement the ISAP and IFRS17 in the course of their work. This IAN is organised into 4 sections and 15 self-standing chapters, discussing the main topics of IFRS 17. Each section has a brief introduction to the topics contained in that section. It is written as a series of Questions and Answers.

This IAN is based on the Standard issued in May 2017 and also reflects some of the discussions held at the February and May 2018 Transition Resource Group (TRG) meetings. In Chapter 12 (Transition) we have based the illustrative dates on an assumed date of initial application of 1 January 2022 as proposed by the IASB in November 2018. This document will be revised in the future to reflect any future changes to the standard by IASB and discussions held at future TRG meetings.

What are International Financial Reporting Standards?

International Financial Reporting Standards (IFRSs), as issued by the International Accounting Standards Board (IASB), are intended to serve as guidance for developing general purpose financial statements and other financial reporting on a globally accepted basis. General purpose financial statements are an important source of information for investors and other users to make economic decisions.

IFRSs are focused on general purpose financial statements of consolidated groups of enterprises but are equally applicable to single societies or companies, be they profit-oriented entities or not-for-profit organisations such as mutual insurance companies. Financial reports in compliance with IFRSs (IFRS-reports) may be prepared voluntarily or their provision may be required, e.g., by state or stock exchange regulations. To be able to make an explicit and unreserved statement of compliance with IFRSs, the financial report needs to comply with all requirements of the relevant IFRSs. The contents of a complete IFRS-report are determined in IAS 1.10.

Some IFRSs are generally applicable (e.g., IAS 1 and IAS 8), some refer to specific circumstances (e.g., IAS 27, IAS 34, IFRS 1, or IFRS 10) whilst others refer to specific subjects (e.g., IAS 19, IAS 37, IFRS 9, IFRS 15 or IFRS 17) and are accordingly of more or less relevance for specific activities within the preparation of an IFRS-report, but considering the need to be in compliance with all IFRSs as noted before.

---

1 IFRSs refers to the ensemble composed by each individual International Financial Reporting Standard (IFRS), as issued by the IASB since 2001, and by each individual International Accounting Standard (IAS), as issued by IASB’s predecessor IASC before 2001, by each International Financial Reporting Interpretation Committee Interpretation (IFRIC), as issued by IFRIC, and by each individual Standard Interpretation Committee Interpretations (SIC), as issued by IFRIC’s predecessor SIC. All these terms are registered trademarks owned by the IFRS Foundation, owning as well the copyright of all IFRSs.

2 IASB, Preface to International Financial Reporting Standards (PRE), September 2010, PRE.6-7

3 PRE.15 and IAS 1.16
What is IFRS 17– Accounting for Insurance Contracts?

The project to develop authoritative guidance for accounting for insurance contracts in IFRS-reports began in 1997. After introducing an interim standard, IFRS 4, in 2002, applicable from 2004 onwards, which allowed a wide scope of accounting approaches to continue to be applied, IASB completed the project in 2017 by issuing IFRS 17 - Insurance Contracts. IFRS 17 may be applied from 2018 onwards under certain conditions and is to be applied for all periods commencing after 1 January 2021 at the latest.

IFRS 17 provides authoritative guidance whether or to what extent items are within the scope of IFRS 17 (subsequently referred to as “classification”) and about recognition, measurement, presentation and disclosure of items within the scope of IFRS 17. IFRS 17 covers insurance contracts, whether issued directly or acquired in the form of reinsurance contracts assumed by the entity. Rights and obligations of policyholders of direct insurance contracts are not within the scope of IFRS 17.

The scope of IFRS 17 refers mainly to insurance contracts, as defined in IFRS 17, as contracts transferring significant insurance risk, irrespective of the laws or regulation of the respective jurisdiction which might classify and regulate other contracts as insurance contracts. Special inclusions or exclusions of some forms of contracts which might meet the defining criteria are provided. Investment contracts with discretionary participation features are also covered by IFRS 17.

Recognition follows typical accounting practice but permits the recognition of future premiums in some cases, where they do not represent a current enforceable right of the entity. For that purpose, IFRS 17 introduces a concept referred to as contract boundary (see Chapter 2) describing whether a future non-enforceable premium might be anticipated or not in the liability determination.

How is the liability for an insurance contract determined?

The measurement under IFRS 17 requires the determination of a current value of the insurance contract, considering market perspectives for financial risks and the reporting entity’s perspective for all other risks, in IFRS 17 referred to as the Fulfilment Cash Flows. This current value is the basis of the measurement of the insurance contract and is to be disclosed. The disclosures include its conceptual parts, the unbiased estimate of the expected present value of future cash flows, which is adjusted for the time value of money and further adjustments applied for financial risks and non-financial risks.

At outset a Contractual Service Margin (CSM) is established to offset any gain, if any, at initial measurement - that is the value of premiums in excess of the value of obligations. This is then recognised as revenue over the period providing coverage. While there is no unit of account defined for the Fulfilment Cash Flows, the unit of account for the CSM are partitions of annual
cohorts, based on at least three different profitability categories, which are part of annual new business and form the unit of account of the CSM.

The described main approach of IFRS 17 is referred to in this IAN as General Measurement Approach (GMA). IFRS17 allows for a simplified alternative approach to be used for contracts of short coverage period (typically not more than 12 months), known as the Premium Allocation Approach (PAA). The PAA is similar to the unearned premium method in that the measurement of the liability for remaining coverage of short duration contracts might be simplified by distributing premiums over the coverage period in line with passage of time or in proportion to expected benefits. The PAA only applies to the part of the total measurement of the contract referred to as liability for remaining coverage, with the liability of incurred claims following the GMA.

Some special guidance applies for certain contracts whose benefits are determined based on indices or other underlying items like surplus (i.e., insurance contracts with direct participation features) sometimes referred to as the Variable Fee Approach (VFA). It includes a feature distributing the insurer's share in changes of financial risk and incurred events over the remaining coverage period of the contract.

Reinsurance ceded is measured using assumptions that are consistent with the ceded contract.

How do insurers present profit or loss statements when applying IFRS17?

The statement of financial performance (profit or loss) is expanded by a section for the insurance service result. This contains as insurance revenue any release of cash flows, except those from investment components, risk adjustments for non-financial risk and CSM from the liability for remaining coverage for the respective period as far as originally resulting from premiums. Actual benefits and expenses of the period, including changes in the liability for incurred claims, but excluding any investment component paid, are presented as insurance service expenses. Changes in the effect of discounting and any other effect of financial risk are presented as insurance finance revenue or insurance finance expenses in the financial result. There is an accounting policy choice to present the effect of changes of financial risk directly in equity (Other Comprehensive Income), potentially avoiding / reducing volatility in the statement of financial performance.

Which specific disclosure requirements are included in IFRS 17?

IFRS 17 includes requirements to disclose information about the amounts recognised in the IFRS-report, particularly requiring reconciliations of presented amounts, significant judgment in determining those figures, including disclosures of the applied interest rate curves and a quantification of the risk adjustment for non-financial risk, and the nature and extent of the risks from the covered contracts.
In applying IFRS 17 for the first time, the standard provides two alternative approaches for transition if the retrospective approach as required by IAS 8 is impracticable. These are a modified retrospective approach and a fair value approach.

There is not a separate chapter on Disclosure in this IAN. Rather, disclosure is discussed in various chapters as relevant.

References to IFRS 17

In this IAN the use of the phrase “Paragraph X” etc. is a reference to paragraphs in IFRS 17. Where paragraphs from other IASs / IFRSs are referenced (e.g., paragraph 28 of IFRS 13) then that International Standard is stated.

In conjunction with IFRS 17, the IASB has published illustrative examples to IFRS 17. The document contains 18 examples applying IFRS 17 to hypothetical situations. Paragraph numbers in the illustrative examples to IFRS 17 are prefixed “IE”.

Interpretations are issued from time to time by the IASB Interpretations Committee (IFRIC). At the time of drafting this IAN there are no interpretations relating to IFRS 17 but one or more could be issued in future.

In this IAN reference is sometimes made to “BC” paragraphs from the IASB “Basis for Conclusions” which accompanied IFRS 17 when it was published. Those paragraphs together with any staff papers issued for TRG meetings, which are also referred to in this IAN, should not be considered as authoritative guidance. Rather they may be considered as background or supportive material.

Materiality

Materiality, in an accounting sense, is a principle that essentially creates a boundary between issues that have an effect on the outcome in an accounting sense and those that have no discernable effect. Judgement is required in determining this boundary, which affects that scope and extent of actuarial analysis for the GMA.

The following comes from paragraph 2.4 of ISAP 1:

In case of omissions, understatements, or overstatements, the actuary should assess whether or not the effect is material. The threshold of materiality under which the work is being conducted should be determined by the actuary unless it is imposed by another party such as an auditor or the principal. When determining the threshold of materiality, the actuary should:

- Assess materiality from the point of view of the intended user(s), recognizing the purpose of the actuarial services; thus, an omission, understatement, or overstatement is material if the actuary expects it to affect significantly either the intended user’s decision-making or the intended user’s reasonable expectations;
Consider the actuarial services and the entity that is the subject of those actuarial services; and

Consult with the principal if necessary.

Proportionality

Proportionality, in an accounting sense, is a principle that determines that the appropriate weights are given to all influences on accounting measures. Again, actuarial judgement has a major influence.

Illustrative examples

In this IAN some examples are provided to help ease of understanding of the topic. It should be remembered that these examples are for illustrative purposes only and each case needs to be considered on its own merits.

Overview of the sections and chapters of this IAN for IFRS 17

Chapter 1 on Classification of Contracts and Contract Boundaries

This Chapter considers approaches to the classification required by IFRS 17, including the identification of contracts, the scope of IFRS 17 and contract boundaries. It refers to other IANs addressing further specific classifications.

Section A – The General Measurement Approach

Chapter 2 on Estimates of Future Cash Flows

This Chapter considers the requirements for determining the estimates of future cash flows whether they be to calculate liabilities for remaining coverage or liabilities for incurred claims. It discusses issues such as which cash flows would typically be included, how those cash flows might be estimated, how the term “current estimate” is defined or what does it mean to be unbiased. The Chapter also refers the reader to the IAA’s monographs on Current Estimates 4 and on Stochastic Modelling 5. This Chapter does not discuss the cash flows particular to contracts with participating features or other variable cash flows which are discussed in Chapter 8.

Chapter 3 on Discount Rates

This Chapter considers the time value of money in the measurement of future cash flows and financial risk. It discusses both the “Top Down” and “Bottom Up” approaches referred to in IFRS 17 for determining yield curves. The Chapter refers to the estimation of risk free rates, the decomposition of credit and liquidity risks, extrapolation of yield curves and investment related expenses. The roles of the discount rate in the measurement of cash flows varying with

---

4 Measurement of Liabilities for Insurance Contracts: Current Estimates and Risk Margins
5 Stochastic Modelling – Theory and Reality from an Actuarial Perspective
underlying items, the determination of interest expense and the interest to be accreted on the CSM are also considered.

Chapter 4 on Risk Adjustment for Non-Financial Risks

This Chapter considers the criteria for, and measurement of, the risk adjustment for non-financial risk required as part of the General Measurement Approach under IFRS 17 including the purpose and general requirements of the risk adjustment, what risks would typically be covered and specific considerations in determining the risk adjustment. This note discusses how to reflect risk mitigation as risk mitigation in a pool, diversification, risk sharing, catastrophic and other infrequent events, qualitative risks considerations, use of different approaches by line of business, and general considerations in selecting and calibrating a risk adjustment approach. For detailed risk adjustment methods and how to apply them, reference is made to the IAA Monograph Risk Adjustments 6. This Chapter also covers high level disclosure requirements including confidence level disclosure, and issues around allocation of risk adjustments to a lower level.

Chapter 5 on Unit of Account

This chapter considers the appropriate level of aggregation when accounting for business under IFRS 17. Amongst other considerations this includes the determination of the unit of account and the setting of portfolios and groups to meet IFRS 17 needs.

Chapter 6 on Contractual Service Margin and Loss Component

This Chapter considers the requirement under IFRS 17 to set up a Contractual Service Margin (CSM) at outset for each group of insurance contracts, including how it should be determined, the subsequent measurement including the allocation of revenue to future periods in line with the provision of services and the treatment of the loss component for “onerous contracts”.

Section B – Variations to the GMA

Chapter 7 for Premium Allocation Approach

This Chapter considers the use of the Premium Allocation Approach (PAA) under IFRS 17 including the criteria to be met for an insurance contract to choose this method, the measurement approach and the differences between this approach and the General Measurement Approach. The Chapter focuses on the “liability for remaining coverage”. The measurement of the contract liability from the point of occurrence of an insured event includes the “liability for incurred claims” which follows the requirement of the General Measurement Approach discussed in other chapters.

6 Risk Adjustments under IFRS 17
Chapter 8 on Participation Features and Other Variable Cash Flows

This Chapter considers the recognition, measurement and presentation of participating features, particularly in the case of contracts with direct participation features, as well as for other cash flows subject to the discretion of the insurer or linked to indices, including the criteria to be met for those classifications.

Chapter 9 on Reinsurance

This Chapter considers the treatment of reinsurance, both held (ceded) and assumed, under IFRS 17; including how to determine if IFRS 17 is applicable to specific reinsurance transactions. It discusses issues related to the separate presentation and valuation of the reinsurance ceded from associated underlying (ceded) contracts, and considerations in determining the estimate of future cash flows, risk adjustments and CSM and allowance for counter party risk on reinsurance ceded. Similar issues are covered for reinsurance assumed.

Section C – Uses of fair value measurement in IFRS 17

Chapter 10 on Fair Value Measurement

This Chapter considers the use of the fair value measurement of insurance contracts for IFRS 17 including for business combinations or portfolio transfers and on transition if the fair value approach is chosen.

It discusses the determination of the fair value of insurance contracts in the context of the more general guidance on fair value measurement found in IFRS 13 Fair Value Measurement and of common insurance industry practices.

Chapter 11 on Business Combinations and Portfolio Transfers

This Chapter considers the requirements under IFRS 17 when accounting for insurance contracts or liabilities for incurred claims acquired in a business combination or a portfolio transfer, and in particular the need to use the fair value of the contracts as the initial consideration. This Chapter considers the interaction between IFRS 17 and the more general guidance found in IFRS 3 Business Combinations and discusses aspects of business combinations, such as the determination of goodwill and the recognition of intangible assets.

Chapter 12 – Transition

This Chapter considers the one-time event of presenting statements applying IFRS 17 for the first time. It has four sections: an overview and then a section for each of the three transition methods described in IFRS 17 – the retrospective approach of IAS 8 and the alternative approaches introduced by IFRS 17, Modified Retrospective and Fair Value. The Chapter has a sample timeline. It also references content from Chapter 15 on Fair Value Measurement.

Section D – other IFRS 17 topics

Chapter 13 on Embedded Derivatives
This Chapter considers the requirements under IFRS 17 for the separation of certain derivatives embedded in contracts subject to the scope of IFRS 17. This Chapter discusses the issues which may arise in detecting and identifying embedded derivatives in such contracts which may need to be separated. Further information about embedded derivatives based on other IFRSs is found in the existing IAN 10 Embedded Derivatives.

Chapter 14 on Contract Modifications

This Chapter considers the treatment under IFRS 17 of contract modification to insurance contracts, including reinsurance contracts, de-recognition and transfer to third parties. It discusses what constitutes a contract modification and what can be simply treated as a change in estimate.

The Chapter describes approaches for determining the deemed premium when treated as a cancellation and replacement of the original contract as well as the application under the PAA. The approaches applicable to future contractual cash flows to be considered due to a prior contract boundary are also outlined.

It also discusses when and how contracts can be derecognised.

Chapter 15 on Measurement, Presentation and Disclosures

This Chapter considers the general requirements for presentation of financial information under IFRS contained in IAS 1 as well as the specific additional requirements in IFRS 17. It also provides general comments on the disclosures required to explain the presentation such as the required reconciliations. Additionally, this Chapter discusses the additional requirements of IFRS 17, including what constitutes revenue and expenses, how experience variances are presented, what is to be reported in the Statement of Financial Performance versus Other Comprehensive Income, the level of aggregation to be used in presentation and disclosure, and required reconciliations.
Chapter 1 – Classification of Contracts

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality.

1 A. What does this chapter address?

This Chapter considers the scope of IFRS 17, the identification and boundary of insurance contracts, separation of components and combination contracts and level of aggregation under IFRS 17 and contract boundaries. It refers to other IANs addressing further specific classifications.

1.B. Which sections of IFRS 17 address this topic?

Paragraphs 2-25, 34-35, 62, 72-74, Appendix A, paragraphs B3-5, B7-18, B24-27, B31-32 & B61, B64, C10, C21 & C23 provide guidance on this topic.

1.C. What other IAA documents are relevant to this topic?

None
Scope of IFRS 17

1.1. Which contracts are covered under IFRS 17?

Paragraph 3 states that the contracts within the scope of the standard are:

a) Insurance contracts (including reinsurance contracts) an entity issues;

b) Reinsurance contracts an entity holds;

c) Investment contracts with discretionary participation features any entity issues, provided the entity also issues insurance contracts.

The definition of an insurance contract is the same as under IFRS 4 and can be found in appendix A of IFRS 17.

“A contract under which one party (the issuer) accepts significant insurance risk from another party (the policyholder) by agreeing to compensate the policyholder if a specified uncertain future event (the insured event) adversely affects the policyholder.”

Insurance contracts held by an entity (i.e., as a policyholder), which are not reinsurance contracts held, are not, however, within the scope of IFRS 17 (see paragraph 7(g)).

While IFRS 4 used the phrase “financial instruments with discretionary participation features”, IFRS 17 refers instead to “Investment contracts with discretionary participation features”. The definition of this term in Appendix A refers in turn to “financial instruments” and so is very similar to that used in IFRS 4.

Appendix A defines an “Investment contracts with discretionary participation features” as

A financial instrument that provides a particular investor with the contractual right to receive, as a supplement to an amount not subject to the discretion of the issuer, additional amounts:

(a) that are expected to be a significant portion of the total contractual benefits;

(b) the timing or amount of which are contractually at the discretion of the issuer; and

(c) that are contractually based on:

(i) the returns on a specified pool of contracts or a specified type of contract;

(ii) realised and/or unrealised investment returns on a specified pool of assets held by the issuer; or

(iii) the profit or loss of the entity or fund that issues the contract

1.2. What is the definition of an insurance risk under IFRS 17?

As noted in 1.1 above, Appendix A of IFRS 17 defines an insurance contract in terms of acceptance of “significant insurance risk”.
Insurance risk is defined in Appendix A of IFRS 17 as “risk, other than financial risk, transferred from the holder of the contract to the issuer”.

Paragraphs B7 to B16 provide guidance on what is insurance risk when applying this definition.

Financial risk as defined in Appendix A of IFRS 17, includes non-financial variables, provided they are not specific to the insurer or policyholder. Paragraph B8 explains this and provides examples.

Even if a financial variable is used in determining the size of a payment, if the payment is significant and dependent upon the occurrence of an insured event, then the contract is an insurance contract (see paragraph B10). An example of this is an index-linked life insurance cover, where the insured death benefit is the difference between the value of the units and the specified death benefit.

An insured event is defined in Appendix A of IFRS 17 as “An uncertain future event covered by an insurance contract that creates insurance risk.”

Paragraphs B3 to B5 provide guidance on what “an uncertain future event” is when applying this definition.

The uncertainty can relate to one or more of the probability, timing or size of the event. Hence, it includes cases where the event has already occurred, but the timing or size of the compensation remains uncertain.

The insurance risk must have an adverse effect on the policyholder and is transferred to the insurer by the insurance contract. Therefore, the policyholder should be already exposed to this risk before the insurance contract is created (see paragraph B11). Lapse, persistency and contract expense risks arising from a contract are for the reasons above not insurance risks.

A contract issued to an entity that covers risks such as lapse, persistency or contract expenses on that entity’s existing portfolio is likely to meet the definition of an insurance contract for the issuer since the entity is the policyholder. Further, if the entity’s existing portfolio includes insurance contracts, not just investment contracts, then such a contract is also likely to qualify as reinsurance held, for the holder of the contract. If there are no insurance policies in the portfolio, the contract does not fall under IFRS 17 for the entity (see paragraphs B14 and B15).

This adverse effect of the uncertain event on the policyholder is a necessary contractual precondition for a contract to meet the definition of an insurance contract. Note this does not require the insurer to investigate if an adverse effect occurred, but just to have the ability to deny compensation if such adverse effect does not exist (see paragraph B13).
The compensation can be a payment in kind by providing goods or services (see question 1.4).

1.3. What is the definition of significant insurance risk?

An insurance contract is only in scope of IFRS 17 if it transfers a significant amount of insurance risk to the entity (or reinsurer).

Insurance risk is only significant if there is at least one scenario with commercial substance where the compensation paid by the insurer is significant, disregarding the likelihood of that scenario. If commercial substance exists only in very unlikely scenarios, but the contract covers all these scenarios, then this qualifies as being significant (see paragraph B18).

Insurance risk can already be significant even if the policyholder still has to opt for insurance cover in the future, but with insurance rates already specified. Also, an insurance contract remains an insurance contract even if the original insurance risk has expired (unless a specified contract modification has occurred (see paragraphs 72 & 74-77).

IFRS 17 requires that the compensation and its commercial substance be considered on a present value basis, unlike IFRS 4, which did not require the use of present values in making this assessment.

1.4. What are examples of contracts that are covered under IFRS 17?

Paragraph B26 gives a list of examples. Most of the items on the list were also on the one in IFRS 4.

Some contracts may not fall under IFRS 17, even though they involve significant transfer of insurance risk. For example:

- Product warranties may otherwise qualify as insurance contracts, but not when issued directly by the manufacturer. These fall under IFRS 15 or IAS 37.

- Life-contingent annuities and pensions may otherwise qualify as insurance contracts, but not when accounted for as part of employers’ liabilities from an employee benefits plan or retirement plan. These fall under IAS 19 or IAS 26.

In addition, for some contracts that meet the definition of an insurance contract, but whose primary goal is to provide services for a fixed fee, paragraph 8 gives entities the option to choose between IFRS 17 and IFRS 15, if the contract meets all of the following criteria:

- the entity does not reflect an assessment of the risk associated with an individual customer in setting the price of the contract with that customer;

- the contract compensates the customer by providing services, rather than by making cash payments to the customer; and
• the insurance risk transferred by the contract arises primarily from the customer’s use of services rather than from uncertainty over the cost of those services.

An example of this type of contract could be roadside assistance.

1.5. What are examples of contracts that are not covered under IFRS 17?

Paragraph 7 sets out contracts that are specifically excluded from the scope of IFRS 17 even if they meet the definition of an insurance contract. This list is similar to the one in IFRS 4; however, it also now explicitly excludes residual value guarantees provided by a manufacturer, dealer or retailer.

In addition, under paragraph 7(i), although financial guarantee contracts remain excluded from the scope of IFRS 17, it now allows an entity that has previously regarded such contracts as insurance contracts and applied insurance accounting on them, the option to use IFRS 17 for such contracts. Otherwise the IFRS relating to Financial Instruments apply (IFRS 7, 9 and 32).

Paragraph B27 provides examples of contracts that do not qualify as insurance contracts. These are unchanged from IFRS 4, although in some cases they have been expanded upon.

The following schematic helps understanding which contracts fall under IFRS 17 or elsewhere.

1.6. Where does the scope of IFRS17 differ from IFRS 4?

The examples in questions 1.4 and 1.5 already include a comparison with IFRS 4.

Under paragraph 3, investment contracts with discretionary participation features are only in scope if the entity also issues insurance contracts. This additional condition was not in IFRS 4. BC85 explains the rationale for this is that for the few entities that issue investment contracts with discretionary participation benefits, but not insurance contracts, the costs of implementing IFRS 17 would outweigh the benefits.
Separation of components from a contract

1.7. When might components of a contract be valued separately?

IFRS 17 distinguishes between insurance components, embedded derivatives, investment components and service components (see paragraphs 10-13).

Embedded derivatives are to be separated following the rules of IFRS 9. Derivatives that can be contractually transferred independently, or have another counterparty, are not embedded, but separate contracts.

Investment components are to be separated if and only if they are distinct, which means that both of the following conditions are met (paragraphs B31 and B32):

- The investment component is not highly interrelated with the insurance component; this means both that the entity is able to measure each component without considering the other components and policyholders can benefit from each component even if the other is not present (e.g., each component can lapse independently).
- The investment component appears after some reasonable research to be, or could be, sold separately in the same market or jurisdiction.

This means for instance that components that necessarily expire together (in case of a death or lapse/cancellation) or that are available in other markets but could not be provided separately in the own market, in general would not be separated.

Service components are to be separated in line with paragraph 7 of IFRS 15, but only after satisfying the requirements of paragraphs B33-35, in which case they are measured under IFRS 15, as modified by paragraph 12 of IFRS 17. To separate service components, fulfilment cash inflows and outflows need to be attributed to either the insurance or service component, with a rational allocation for those cash flows that are not uniquely related to either of these two (see paragraph 12).

1.8. What are examples of components that are currently often separated, but can no longer be separated under IFRS 17?

Insurers have currently often different components, such as claims liabilities to be settled, unearned premiums, receivables/payables, etc managed separately and administered in different systems. IFRS 17 leads to insurance receivables, policy loans and reinsurance collateral (funds withheld) no longer being separately visible on the balance sheet.

BC114 gives policy loans, assuming that they are a contractual feature, as an explicit example of a component highly interrelated with the rest of the contract and therefore not separable in a non-arbitrary way.
Contract boundary

The contract boundary distinguishes future cash flows to be considered in the measurement of the insurance contract from other future cash flows, even if they are expected to be paid under the same contract (see paragraphs 34 and B61). The contract boundary determines where a contract ends for measurement purposes, for a reporting period.

1.9. What is the definition of a contract boundary under IFRS 17?

Paragraph 34 defines the boundary of a contract for IFRS 17 measurement purposes.

“Cash flows under IFRS 17 are within the boundary of a contract if they arise from substantive rights and obligations that exist during the reporting period in which the entity can compel the policyholder to pay the premiums, or in which the entity has a substantive obligation to provide the policyholder with services.”

1.10. What are “Substantive rights and obligations”? 

Paragraph 2 makes it clear that:

- rights and obligations arise from contract, law, or regulation; and
- enforceability of rights and obligations is a matter of law.

It applies the term “substantive” to identify when future cash flows arising from those rights and obligations can be recognised as assets or liabilities. Accordingly, all clear cases of present enforceable rights or present enforceable obligations, as discussed in BC160, are within the contract boundary, if they are substantive. Any terms that have no economic substance are disregarded.

According to paragraph 34, substantive rights and obligations “exist during the reporting period in which the entity can compel the policyholder to pay the premiums or in which the entity has a substantive obligation to provide the policyholder with services”.

Cases where no party has any right may be outside the contract boundary (see BC160 (a)). This is particularly the case if both parties have an unlimited cancellation right or no party has a renewal right.

If the policyholder, cannot be forced to pay the premium, e.g., if the policyholder is not obliged to renew a contract with an agreed upon duration, there is no substantive right of the entity to premiums after the agreed duration.

A substantive obligation could be present in cases where the applicable terms and conditions can cause future cash flows, compared with alternative cash flows within the contract boundary or premium component, to be onerous without the insurer having the ability to avoid such losses due to the absence of any cancellation or premium or benefit
adjustment right. In that case, the guidance of paragraph 34 is likely to require that the loss is anticipated.

For example, in the case of a contractual clause that the funds of the contract might be used to purchase an annuity where the assumptions regarding longevity could be adjusted to represent the individual longevity risk, but not beyond that, the annuity is normally not within the contract boundary. If the terms and conditions determine a contractually fixed annuitisation rate, however, then the entity is likely to be subject to a substantive obligation and the loss-making annuitisation of the funds might be anticipated, considering the likelihood that the annuity will be elected. That might also apply in cases where a premium component, with a unilateral right of the policyholder to pay the premium in future, includes minimum financial guarantees that are in the money at the reporting date and the adjustment clauses would not allow the entity to avoid that loss if the policyholder decides to pay the premium.

Paragraphs 34 (a) and (b) describe two alternative cases of when a substantive obligation ends. Accordingly, to show that a future contractual cash flow is not a substantive obligation, it is necessary to demonstrate that it arises from (or after) a period for which one of the following cases apply:

a) the entity has the practical ability to reassess the risk of a particular policyholder and can set a price accordingly; or

b) both of the following conditions are satisfied:

   i) The entity has the practical ability to reassess the risks at a portfolio level and can reset the price or level of benefits accordingly; and

   ii) The pricing of the premiums for coverage up to the date when the risks are reassessed does not take into account the risks that relate to future periods.

1.11. What does it mean to have the Practical Ability to reassess the risk?

The reference to the “practical ability” to reassess the risk is intended to differentiate from a pure formal legal right to do so, but where practical facts and circumstances actually prevent the entity from doing so. For example, it might be practically impossible to assess the risk due to any or all of the following:

- inaccessibility of the item bearing the risk;
- moral reasons;
- significant cost; or
- significant business dangers.
It is not the expectation that the entity does not intend to apply the reassessment but only the expectation that, even if it wishes to do so, it would not be able due to practical reasons.

Paragraph B64 notes that practicable ability exists if the entity can reprice the contract or portfolio (as applicable) to the same price it would charge for a new contract or portfolio with same characteristics. If an entity decides to charge a new price for new contracts, but for commercial reasons decides not to do so for existing contracts, then further judgment is required to assess whether this commercial decision was a free choice or refers to a practical inability to reprice. (see paper AP03 to May 18 TRG.)

1.12. What does it mean to reassess the risk of a particular policyholder?

When considering whether or not there is a substantive obligation, the entity may consider if there is any risk of anti-selection by the policyholder on the specific financial risk transfer. For instance, because of a possibly impaired risk profile it might be advantageous for the policyholder to continue the existing contract rather than effect a new contract. This advantage affects the substantive obligation of the entity to provide services.

The conditions outlined here might only be understood by considering the underlying risk for the ‘particular policyholder’ and cannot be assessed based on collective information. Therefore, under paragraph 34 (a) this can be interpreted to refer to risks transferred from the policyholder, insurance and financial risk only. The substance of the obligation results from guaranteed insurability or minimum guarantees on participation contracts.

1.13. What does it mean to reassess the risks at a portfolio level?

This is more than the ability to reflect general market experience, it requires the ability to reflect the experience of the portfolio itself. Again, the risks being reassessed are policyholder risks, transferred from the policyholder, e.g., insurance and financial risks not lapse and expense risks created by the contract even though they would be reflected in pricing (see paper AP02 to February 2018 TRG).

1.14. When does an obligation take into account the risks that relate to future periods?

The condition in paragraph 34(b) refers to substantive obligations arising from premiums already paid in the past even in the case of a collective premium or benefit adjustment clause. If there are none, as outlined in paragraph 34 (b) (ii), there is no substantive obligation in this case. This is typically the case if the entity charges premiums only to finance services in the premium payment period and the premium or benefit adjustment clause refers to future premiums financing the services in future periods entirely without support from already paid premiums. If the entity charged premiums in the past which included parts intentionally considered to finance coverage together with future premiums, those past premiums result in a substantive obligation of the entity, even if the future premiums are subject to a collective premium or benefit adjustment clause.

Paragraph 34(b) reflects two of the common types of premiums:
a) those which are often referred to as “yearly renewable” that only cover the risk arising in the next period e.g., one year (no substantive obligation); and

b) level premiums for the whole contract which in any one year might be greater or less than the cost of the risk for that next year with any excess premium being used to help “finance” the cost of risk in a later period (substantive obligation).

1.15. What is the consequence if a future cash outflow is outside the contract boundary, but not the originating premium?

This situation occurs if the future benefits are to be provided in the form of another service, e.g., an investment contract with an option to purchase an annuity with proceeds at maturity (see paragraph B24). In this case, the option to purchase an annuity, means the provision of an annuity is part of the contractual terms of the investment contract and it has significant insurance risk at inception. As noted in paragraph 24, however, if the contract as a whole is able to be repriced (as per paper AP03 to May 2018 TRG), which is the case here, when it becomes an annuity, and it is repriced to the then current terms for new entrants, then the annuity and associated provision of insurance coverage is outside the contract boundary. If terms of conversion to annuity are fixed at inception of the investment contract, the insurance coverage is within the boundary of the investment contract and the contract at inception, not just when annuity option is exercisable, is an insurance contract.

1.16. What are the issues for contract boundaries under reinsurance?

Paragraph 34 cannot be applied as it is, because in reinsurance held it is the entity who pays the premium (substantive obligation) and receives services (substantive right). In accordance with paragraph 4 (and TRG paper 3 of February 2018 and paper 4 of May 2018), the reading of this paragraph needs to be adapted appropriately to the context of reinsurance held. The contract boundary is then, the earlier of:

• when the reinsurer can reassess the services, thereby ending the substantive right of the holder of the reinsurance to receive the service; and

• the insurer is no longer compelled to pay a premium, thereby ending the substantive obligation.

When a direct insurance contract is being reinsured, differences in the boundaries of both contracts may occur, due to reinsurance and underlying insurance contracts having different dates of initial recognition. For example:

• A new reinsurance contract may cover insurance contracts that existed prior to the reinsurance contract coming into effect; or

• The scope of the reinsurance contract may extend to include future insurance contracts yet to be issued within the boundary of the reinsurance contract.
The February 2018 TRG meeting in its discussion of paper AP03, observed that expected future contracts could be within the boundary of the reinsurance contracts. Note, Paragraph 62 only requires that a proportionate reinsurance should not be recognised earlier than the initial recognition of any underlying contract and does not determine the boundary of the reinsurance contract.

Also, reinsurance contracts sometimes provide the reinsurer with cancellation options that are more flexible than in direct insurance and care is needed in assessing the boundary of such a reinsurance contract.

1.17. What are other boundary situations that need separate consideration?

Paragraph 35 states that expected future cash flows, which are not within the contract boundary, relate to future contracts. The standard does not make a distinction between the situation where such cash flows are highly interrelated with the existing contract, or not.

A typical situation is an insurance contract with a unit linked account and an insurance rider with the annual stepped rider premiums deducted from the unit linked account. As the units are repriced daily to market, they do not create a substantive obligation. If the rider premiums can be repriced at the portfolio level at annual renewal, then substantive obligation for insurance ends at annual renewal and boundary for the contract, as a whole, is the annual renewal date (see AP02 February 2018 TRG). In general, the cash flows arising from these future premiums are then considered as being outside the contract boundary.

Future insurance contracts

Under paragraph 35, future premiums, and the cash flows arising from them, would then relate to future contracts. Since contracts can be combined in groups issued no more than one year apart, this would mean that each set of annual premiums and associated cash flows would need to be treated as a separate contract under IFRS 17.

This has significant implications if the cash flows resulting from paid and future premiums are highly interrelated, for instance:

- Acquisition expenses for the contract as a whole; acquisition expenses are allocated to the initial contract created by premiums paid up to annual renewal, except to the extent they are dependent on renewal of the contract, e.g., acquisition commission subject to clawback if the contract is not renewed, can be allocated to the future contract created by the renewal (see AP04 February 2018 TRG). This could likely lead to an onerous “first” contract comprising the first premium only and to several very profitable contracts related to future premiums afterwards;

- In some instances, a rider cost may be funded from an investment component built by paid premiums. The risk premiums extracted from each “premium layer” contract will need to be reconsidered every time a new premium is paid.
Also, it may be technically possible that such “new” contracts are not in the scope of IFRS 17, e.g., right to insurance cover is not available in later years of the contract.

Paragraph 25 requires that the “new” contract is recognised at the earliest of:

(i) the beginning of coverage period;
(ii) the date of the first payment; and
(iii) the moment that the contract becomes onerous.

So, for a non-onerous contract, a new right or obligation could occur before the first related payment, and when treated as a new contract, the rights or obligation should then already be considered before the payment date.

1.18. When should a contract boundary be reassessed?

Paragraph 64 states that the boundary of a contract should be reassessed at the end of each reporting period, in order to include the effect of changes in the substantive rights and obligations of the entity.

It might be argued, in our example of future premiums being outside the current boundary of a contract, that any new premium paid could be seen as “crossing” the existing boundary and extending the new boundary by including the newly received premium and all related cash flows.

Aggregated levels of insurance contracts

IFRS 17 defines different levels at which insurance contracts can or should be aggregated.

<table>
<thead>
<tr>
<th>Portfolio</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group of contracts</td>
</tr>
<tr>
<td>Combine contracts</td>
</tr>
<tr>
<td>Contract</td>
</tr>
</tbody>
</table>

In this section we discuss each of these levels.

1.19. When should contracts be combined for measurement purposes?
Paragraph 9 states that contracts may need to be combined and treated as a whole, in order to report their substance, if they have the same or related counterparty and as a set achieve, or are designed to achieve, an overall commercial effect. Paragraph 9 gives the example of two contracts that negate each other. This was discussed at the May 18 TRG, see paper AP01 and the TRG observed that:

- A single legal contract would generally be considered on its own to be single contract in substance, but there may be circumstances when a set of contracts are in substance one contract;

- Determining this requires careful judgement and consideration of all the relevant facts and circumstances, and no single factor is determinative in making this assessment;

- Considerations that might be relevant include:
  - Rights and obligations are different when looked at together compared to individually. For example, rights and obligations in one contract may negate those in another;
  - One contract cannot be measured without considering the other, e.g., the contracts are highly interrelated;

- An existence of a discount, of itself, does not mean that a set of contracts are designed to achieve an overall commercial effect.

If the assessment leads to the conclusion that paragraph 9 applies, then the contracts as a whole need to be combined.

1.20. What is the meaning of “portfolio of insurance contracts” in IFRS 17?

A portfolio comprises contracts subject to similar risks and managed together. Paragraph 14 also notes that contracts within a “product line” would be expected to have similar risks and hence be in the same portfolio if they are managed together.

1.21. What does it mean that “contracts have similar risks”?

In general, IFRS 17 and its Basis for Conclusions contain several sections related to this question. The relevant wording in paragraph 14 is as follows:

A portfolio comprises contracts subject to similar risks and managed together. Contracts within a product line would be expected to have similar risks and hence would be expected to be in the same portfolio if they are managed together. Contracts in different product lines (for example single premium fixed annuities compared with regular term life assurance) would not be expected to have similar risks and hence would be expected to be in different portfolios. “If contracts cover similar risks and are within the same product line, they are subject to similar risks”
"Similar" does not mean "identical". Some variation in risk is reasonable, as long as the contracts are sufficiently similar. Since insurance is diverse and all portfolios are different, no prescriptive guidance can be provided on the correct level of materiality for the definition “of similar” and the decision process is likely to be entity specific.

Note that IFRS 17 discusses similar risks, which may not necessarily have the same interpretation as “similar insurance risks”. Therefore, an entity may consider other risks such as lapse and expense risk in their determination of what similar risks means.

1.22. What does “managed together” mean?

Again, there is no clear definition in IFRS 17 for this term. Hence judgement is required on what constitutes managed together.

From a practical perspective, the considerations relating to subject to similar risks noted above will require a level of granularity in assignment of portfolios that, in many cases, could result in portfolios that are naturally managed together.

It is expected that the determination of the portfolio level will vary between entities, due to different sizes and complexity, as well as the different ways in which business is managed. A practical approach to determining the portfolios for an entity might rely on the internal management reporting systems. For example, an entity’s internal management systems may consolidate results into product lines. These product lines could provide a suitable aggregation of similar risks; furthermore, an entity may have its systems aligned with its internal management structure and may disclose to the market on that basis. This might constitute a suitable aggregation basis for what is considered as ‘managed together’.

Other factors to consider against the test of managed together could, amongst others, include:

- distribution channel(s) that the contracts are sold through;
- the level at which regulation takes place, for example Compulsory Third Party insurance in Australia;
- capital allocation basis; and
- the operating model or management structure of the entity, including how management incentives are structured.

Product line groupings as prescribed by prudential regulators may not necessarily be appropriate to define portfolios due to a different focus in IFRS 17. The latter’s primary focus is about reporting appropriate profits and losses (BC119) rather than solvency focus of prudential regulators.
Note that an entity may change how it manages its business over time. As a result, the number of portfolios may change over time. This is an anticipated response under IFRS 17, although it does not necessarily affect the number of groups as historical groups do not change and groups are a sub-set of the portfolios.

1.23. What are the potential impacts of an entity’s choice of portfolio?

The definition of portfolio has an impact on:

- further grouping of contracts, which can only be done within a portfolio;
- the level at which entities can make an accounting policy choice determination to reflect all insurance finance income or expenses in profit or loss or disaggregate it between profit or loss and other comprehensive income. This comes from the fact that the IASB assumes that each portfolio has its own portfolio of assets backing the insurance contracts (see BC42 to 44).
- Expenses included in measurement as they need to be directly attributable at portfolio level (see paragraphs B65(e) & B66(d)).

It is important to remember, however, that the significance of insurance risk should not be considered at portfolio level, but still in relation to individual contracts (see paragraph B22 and BC 79).

Groups of contracts

1.24. What are the requirements for contracts in the same portfolio to be grouped together in a group of insurance contracts?

Please see Chapter 5 where this is discussed.

1.25. What if cash flows are measured at a higher level than the group of contracts or portfolio?

Please see Chapter 2 where this is discussed.
Section A – Introduction to the General Measurement Approach

This section includes five chapters that cover the technical aspects of the General Measurement Approach (GMA).

These areas are:

- Estimates of Future Cash Flows (chapter 2);
- Discount Rates (chapter 3);
- Risk Adjustment (Chapter 4);
- Contractual Service Margin (Chapter 6).

There is an additional explanatory section on Levels of Aggregation of Contracts for the use of the GMA (Chapter 5).

When considered together these are often referred to as the “Building Block Approach” as shown below:

1. Unbiased estimate of future cash flows
   - The estimates of cash flows used to determine the cash inflows and outflows relevant to the fulfilment of the insurance contract. These estimates should be explicit, unbiased and probability-weighted.

2. Discounted to balance date
   - At “risk free” plus illiquidity adjustment for most contracts, the discount rate reflects the characteristics of the insurance liability and is consistent with relevant observable market inputs for each reporting period.

3. Add risk adjustment
   - An adjustment to reflect uncertainty in future cash flows relating to non-financial risk.

4. Allow for profit/loss effect
   - CSM eliminates the recognition of any future accounting profit at inception. CSM cannot be negative (i.e. the present value of any onerous contract must be charged immediately to losses). CSM is spread over the remaining coverage period.
What are the building blocks that make up the General Measurement Approach?

Paragraphs 29-52 provide guidance on this topic. BC 18-26 and BC 36-119 also provide background on the GMA.

The IAA has published a paper on Current Estimates (Measurement of Liabilities for Insurance Contracts: Current Estimates and Risk Margins) – see, in particular, Chapter 2, and monographs on Discount Rates (see Chapter 3) and on stochastic methods that may be useful for this purpose. More recently, a monograph on Risk Adjustment was released in May 2018 (see Chapter 4). In general, we do not repeat material from any of the monographs in this IAN. In addition, the general educational material of IAA members provides significant educational material on the different ways to estimate future cash flows. All of this educational material may be relevant.

The following paragraphs provide educational material on the use of the various “building blocks” that make up the GMA in measuring a group of insurance contracts on initial recognition, and subsequent measurement. There then follow five chapters providing more in-depth educational material on individual aspects of the measurement model in greater detail.

Given the principle-based nature of IFRS 17, there is potential for differing interpretations of the various building blocks. Consequently, it is possible that comparison between reporting entities may reveal inconsistencies. Further, definition of the various building blocks may include either “overlapping” (or double-counting) of various aspects of the building blocks, or “gaps” (or omissions of certain elements). The scope of the actuary’s assignment may include responsibility to ensure that the building blocks are appropriately constructed, and that no such overlaps or gaps occur. Some examples of potential situations for differing interpretations follow:

a) In defining the “estimates of future cash flows”, IFRS 17 refers to “the expected value (i.e., the probability-weighted mean) of the full range of possible outcomes” (Paragraph 33). However, in the Basis for Conclusions for IFRS 17, the reporting entity is led towards use of “all reasonable and supportable information available without undue cost or effort about the future cash flows” (BC 18).

In practice, therefore, judgement will be needed, particularly in the incorporation of the extremes of the potential distribution of outcomes. For instance, estimates of certain extreme outcomes may not be supportable, and may need to be included by way of a subjective adjustment. Even if it is judged that such an adjustment would not be material to the expected value of the future cash flows, the impact on the risk adjustment may still be material.

b) In defining an adjustment for the “time value of money”, IFRS 17 incorporates the need to allow for “the financial risks associated with the future cash flows” (BC 19), hence arriving
at a risk-adjusted rate of discount. However, it also recognises that certain insurance contracts may combine financial and non-financial risks in such a way that “those components are interrelated” (BC 18). Hence, there is potential for the adjustment for the time value of money to exclude financial risk adjustment.

Judgement is needed in setting the barriers between the risks to be included in the discount rate.

c) In defining the “risk adjustment for non-financial risk”, IFRS 17 does not separately define non-financial risk and effectively defines it by reference to “financial risk”, the definition of which leaves room for judgement (See Chapter 4 for background).

Again, this leaves room for judgement in setting the barrier between financial and non-financial risk.

d) The illiquidity risk may be included in the discount rate, or alternatively it can be allowed for as part of the risk margin (See Chapter 3 for background).

The risk culture of the entity may inform the constitution of the building blocks, including:

- The perceived boundary between reasonable and unreasonable (i.e., spurious) cash flow projection in relation to the insurance contracts;
- The pricing bases for insurance products;
- Treatment of any asset and liability mismatch allowance/reserve, since this can be represented in different ways; and
- The cash flows and risks within the boundary of the contract under IFRS 17 and those used for other purposes.
Chapter 2 – Estimates of Future Cash Flows

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality

2.A. What does this chapter address?

This chapter provides information concerning the estimates of future cash flows for use in measurement of liabilities and assets arising under contracts within the scope of International Financial Reporting Standard (IFRS) 17 Insurance Contracts. This applies both at issue of the contract and at subsequent measurements.

2.B. Which sections of IFRS 17 address this topic?

Paragraphs 33-35 and B36-B71 provide guidance on this topic.

BC 146-184 also provides background on the subject.

2.C. What other IAA documents are relevant to this topic?

The IAA has published monographs on Current Estimates (Measurement of Liabilities for Insurance Contracts: Current Estimates and Risk Margins) and on stochastic methods (Stochastic Modeling) that could be useful for this purpose. In general, we will not repeat material from either of these monographs in this chapter.

In addition, the general educational material of IAA members provides significant educational material on how to estimate future cash flows. All of this educational material could be relevant.
General Issues:

2.1. What are the requirements of IFRS 17 regarding the measurement of estimates of future cash flows?

Paragraph 33 includes the key characteristics of the measurement of estimates of future cash flows, namely they:

i. Include all future cash flows within the contract boundary

ii. Are the probability weighted mean of the full range of possible outcomes

iii. Are unbiased (i.e., they do not include the risk adjustment for non-financial risk),

iv. Reflect the perspective of the entity (except that estimates of market variables are consistent with observable market variables for those variables)

v. Are current

vi. Are explicit

In estimating future cash flows, the actuary may need to adjust the results to reflect the specifics of the entity for which the cash flows are being estimated. For example, different entities may have different underwriting or claim settlement practices that might affect the estimated future cash flows. While past experience may reflect the practices in effect at the time, if the entity has made changes to those practices, past experience may need to be adjusted for the changes.

2.2. What are the common types of cash flows to be included?

Cash flows referred to in IFRS 17 are primarily payments of cash exchanged between the parties under an insurance contract in accordance with the terms and conditions of the contract. The term “cash flow” can also be used as shorthand for other transfers of economic resources (cash flow equivalents) that are not settled in cash between the parties to the insurance contract. They may also include such items as administration costs, certain overheads (per B65), payments to third parties and non-cash transactions such as the provision of goods and services.

Some non-cash transactions may be subject to other IFRSs that determine the amount of transfer of resource caused by fulfilling the contracts in the respective period. Measurement of future cash flows accordingly includes the allocation or transfer of resources to those future periods under the applicable IFRS.

Future cash flows may refer to any component of the insurance contract that is covered by IFRS 17 excluding separated components. Cash flows do include components that might sometimes be seen as separate but are not separate under IFRS 17 (e.g., policy riders or policy loans). See chapter 1 Classification for additional discussion of this topic.

Paragraph B65 states:
"Cash flows within the boundary of an insurance contract are those that relate directly to the fulfilment of the contract, including cash flows for which the entity has discretion over the amount or timing."

(See chapter 1 Classification for more on contract boundaries).

These cash flows include, but are not limited to:

- Premiums;
- Payments to (or on behalf of) policyholders including
  - claims that have been reported but not yet paid;
  - Payments that depend on the performance of underlying assets;
  - Payments from embedded derivatives; and
  - Incurred claims that have not yet been reported;
- Payments on future claims on unexpired risks;
- An allocation of insurance acquisition costs;
- Claim handling costs;
- Costs the entity will incur for payments in kind;
- Policy administration and maintenance costs;
- Transaction-based costs such as premium taxes and levies;
- Taxes paid in a fiducial capacity to meet obligations of the policyholder;
- Potential cash inflows from recoveries;
- An allocation of fixed and variable overheads directly attributable to fulfilling insurance contracts.

Sometimes, it might be permissible (e.g., due to immateriality) to also consider cash flows exchanged between the parties under the contract not based on the actual payment date but based on a due date or the date when the triggering event incurs.

2.3. At what level are cash flows determined?

Cash flows are generally identified at the individual contract level if possible (e.g., not for claims not reported). For measurement purposes, however, contracts are aggregated into portfolios and groups of contracts (chapter 5 on Unit of Account for more on this). IFRS 17 allows, moreover, the entity to estimate the cash flows at whatever level of aggregation is most appropriate from a practical perspective. If the entity makes estimates at a higher level, it needs to be able to allocate those estimates to groups of insurance contracts so
that the appropriate amounts are included in the measurement of the groups of insurance contracts’ fulfillment cash flows for remaining coverage and incurred claims.

Assumptions may be derived at aggregation levels that are different from the aggregation level applied for measuring contracts. In that case, judgement will be needed to determine what adjustment, if any, is needed to apply them at the required aggregation level. For example, maintenance expenses may be determined for all life insurance contracts, but separate assumptions may be needed for term insurance and whole life contracts.

In some cases, particularly for general insurance contracts covering multiple risks and/or perils, it may be helpful to analyse the experience separately for each of those multiple coverages. Such separation, for analysis and projection purposes, is particularly appropriate where the balance of coverages varies from contract to contract within a line of business, such as small business package policies. Such coverage cash flows may then be combined at the contract level (if practical and useful) before contract cash flows are aggregated into groups and portfolios for measurement purposes. Similar concerns will also apply to life insurance contracts with multiple risks (e.g., mortality and disability) or groups of insurance contracts with multiple durations (e.g., 10, 20 and 30-year term in the same group of insurance contracts).

In summary, BC117 states: “IFRS 17 allows an entity to estimate the fulfilment cash flows at whatever level of aggregation is most appropriate from a practical perspective. All that is necessary is that the entity is able to allocate such estimates to groups of insurance contracts so that the resulting fulfilment cash flows of the group comply with requirements of IFRS 17.” Paragraph 24 gives effect to this.

Issues concerning the definition of cash flows to be included

2.4. What is a current estimate?

A current estimate at the report date is the entity’s estimate based on currently available information in a manner consistent with relevant accounting guidance. The term “current estimate” is used in this chapter as a short form for the “current unbiased estimate of the future cash flows”.

IFRS 17 defines the term “fulfilment cash flows” as including the risk adjustment for non-financial risk (herein shortened to “risk adjustment”) and the effect of discounting. This chapter, however, does not refer to issues regarding calculating present values but focuses on the identification of cash flows and estimating unbiased expected values of those cash flows.

2.5. What is the meaning of expected value?

For IFRS purposes, “expected value of cash flows” represents the mean of the (typically unknown) probability distribution of cash flows. In line with this mathematical concept, IFRS 17 requires that conceptually all scenarios are covered in determining the value of the
cash flows, including scenarios in the extreme tails of the distribution. Where the variability in future cash flows follows a symmetric distribution, actuaries may conclude that the impact and likelihood of favourable and unfavourable extreme scenarios not explicitly considered in a model may broadly offset each other; however, where the distribution of future cash flows is skewed it may be necessary to adjust the expected value to reflect extreme scenarios not allowed for in the model.

For example, the probability distributions of general insurance property claims tend to be positively skewed. The available data for similar products may not be sufficient to fully reflect the future impact of abnormally large claims. In these situations, it is often necessary to rely on other sources of data and judgement to adjust the models. This tends to increase the expected value to reflect these high-cost but low frequency events. Similarly, actuaries may consider it appropriate to take into account favourable extreme scenarios such as, for life insurance, a fall in mortality rates if an affordable cure for cancer is developed. All such adjustments would require judgement on the likely impact and probability of occurrence to adjust the modelled expected value.

The reference in IFRS 17 to scenarios is about the defining characteristic of the mean value of a distribution function rather than providing guidance regarding how to estimate the mean value. It does not require that all possible (or even any) scenarios be explicitly constructed nor is it expected that entities will develop stochastic models for all IFRS 17 reporting.

2.6. Does the distribution function of cash flows need to be determined?

Not necessarily. The accounting purpose is to derive a current unbiased estimate of the expected value of cash flows. There are a variety of approaches that can be used for this purpose and IFRS 17 does not provide any guidance regarding how the estimate is to be made. Any statistical or non-statistical approach applied in determining figures for an IFRS report needs to comply with general accounting requirements as outlined elsewhere in this chapter.

2.7. What does “unbiased” mean?

According to BC 148ff, unbiased estimates:

a) Capture information about the full range of possible outcomes,

b) Should not have an intention of attaining a particular outcome, or

c) Influencing a particular behavior

Therefore, an unbiased estimate does not include either conservatism or optimism.

2.8. How does the object for current estimates as intended by IFRS 17 differ from objectives used for other purposes?

IFRS 17 calls for an estimate of the statistical mean, rather than the statistical median or mode. Other descriptions, such as best estimate or best estimate plus a margin, used in
other accounting structures, may not be the same. Before using cash flows developed for other purposes, their fitness for reporting under IFRS 17 may need to be assessed.

2.9. How are cash flows that do not directly belong to the contract, but are contractual, distinguished from cash flows belonging to the entity in general?

Cash flows belonging to the contract are those that are specifically generated because the contract is in existence (e.g., benefits, commissions, direct administrative expense). Indirect administrative expense, including general overheads, are included only if they are directly attributable to fulfilling a portfolio of insurance contracts as per paragraphs B65(l) and B66(d). If they are not, they are general expenses of the entity not belonging to the contract and are thus not considered in estimates of future cash flows of the contracts.

IFRS 17 is silent with respect to techniques to be used for estimating cash flows, therefore no special techniques are required to determine these indirect expenses included in future cash flows. Methods used for pricing or other types of reporting might be usable for this purpose so long as the result meets the requirements of IFRS 17.

Any cash flows or costs of the entity related to other standards are not discussed in this chapter. When investment administration expenses are estimated, only expenses that are required by the contract are included, not the expenses of the actual investments of the entity. Under normal circumstances, investment expenses are not included in the estimate of future cash flows. An exception to this may apply when those investment expenses are required by the insurance contract.

2.10. To what extent do the estimates of future cash flows have to differentiate contracts with different characteristics (e.g., age, gender), and other known differences of contracts?

Statistical estimates are usually only differentiated for a limited number of characteristics of the item to be estimated and include the average effect of other characteristics. IFRS 17 does not require the entity to assess all characteristics of a contract that might be relevant to the outcome and establish estimates on that basis. Paragraph B37 does require consideration of “all reasonable and supportable information available at the reporting date without undue cost or effort.”

Accordingly, it is a matter of judgment as to what degree characteristics of individual contracts are considered in estimating future cash flows. It may be appropriate for individual contracts to be aggregated into groups of contracts that are not further distinguished. B37 does note, however, that “information available from an entity’s own information systems is considered to be available without undue cost or effort.”

Paragraph 17 may require identification of the fulfilment cash flows of an individual contract for the purposes of initial grouping. Accordingly, assumptions that are appropriate for that purpose would need to be chosen for each contract. It is necessary to determine the degree to which the assumptions are differentiated for the characteristics of individual contracts. The individual characteristics of each contract are only considered to the extent that the assumptions are differentiated on the basis of those characteristics.

The actuary may consider a wide range of factors in an internal experience analysis used for determining liabilities for remaining coverage and incurred claims. This consideration
is to determine whether it is appropriate to incorporate those factors explicitly into the analysis and whether it is appropriate to then incorporate them into the measurement. Factors need not be incorporated in the analysis unless there is reason to suppose that they can reasonably be collected and used by the insurer without undue cost and that they are likely to materially impact the measurement of the fulfilment cash flows of the groups of insurance contracts.

Many characteristics of contracts will not be available to the entity in any case. For other characteristics, even if known, the entity might not be able to assess their impact due to limited statistical data or the undue cost or effort to obtain them. Other characteristics of contracts will not be consistently available for all contracts and, as a consequence, may be ignored since they can only be averaged over other contracts. Other characteristics, which might be assessable at outset or are even assessed, might be ignored in pricing since the overall benefits from such a differentiation would not outweigh the cost of doing so. For example, certain medical examinations or adjusting information systems to differentiate a certain characteristic could be more expensive than the price effect. An entity might thus limit the differentiation of contract characteristics to a certain number that can reasonably be administratively and statistically managed.

Accordingly, for estimating the liability for remaining coverage, the differentiation of assumptions as applied to individual contracts might start with the differentiation used for pricing. Less differentiation than applied in pricing might, if applied to individual contracts, result in inconsistencies between premiums and the measurement of the related cash outflows, if the cash flows are based on averaged assumptions while the associated premiums are more differentiated. For example, a contract viewed in pricing as being riskier and accordingly having a higher premium, would be compared with an average risk and therefore would show a high CSM (unless offset by a higher risk adjustment) while a contract seen in pricing as less risky and accordingly having a lower premium would result in comparison with the average risk, resulting in a low CSM or even showing a contract as onerous.

There are exceptions to this principle. Paragraph BC135 (a) refers to an “intentional pricing strategy”. If the entity underprices certain contracts intentionally, e.g., to gain market share, by ignoring certain relevant and known characteristics of the contracts, it might have the same consequences as if the entity chooses to charge insufficient premiums. Accordingly, measurement considers those peculiarities of the respective contracts and differentiates assumptions on that basis. As a consequence, the premiums agreed for that contract might turn out to be insufficient to cover the value of the risk.

Furthermore, paragraph 20 allows an exception for grouping, where law or regulation constrains the use of specific characteristics for pricing (e.g., where pricing of annuities must be on a unisex or gender-neutral basis). In such cases, the insurer may include such contracts in the same group, but only if they would otherwise fall into a different group due solely to the regulatory pricing constraints. Note that this does not allow those specific characteristics to be ignored in the measurement process, only for grouping.

It is acceptable to allow for the average impact of considered characteristics for the contracts in a group, so that only the average impact of the characteristics is reflected in the measurement, provided that it reflects the true mix of such characteristics in the group.
If the composition of a group changes, however, it may be necessary to reassess the average impact, so that it continues to reflect the mix of characteristics in the group.

Inflows

2.11. What are the cash inflows to be considered?

All cash inflows arising under rights of the insurance contracts and relating to services provided within the contract boundary are considered. The primary inflow is, of course, premium. Investment income, other than that related to policy loans (see below), is not included since it is a cash inflow due to investments and not specifically related to the fulfilment of the contracts.

Other cash inflows considered include such items as salvage, subrogation, contract charges such as cost of insurance charges, and claw-backs of agent commissions originally paid related to the contract. The treatment of such recoveries is not specified in IFRS 17. Any actuarial estimates of such recoveries need to be consistent with their accounting treatment to avoid double counting or omission of these cash flows.

Cash inflows on insurance riders and future insurance options, such as disability premium waiver, hospitalisation, term insurance, guaranteed future insurance (including cash flows from the expected exercise of such guarantees) will also be included if they are related to services provided within the contract boundary. See chapter 1 for more on contract boundaries.

2.12. How are policy loans and repayments handled?

If policy loans are a component of the insurance contract (i.e., terms are guaranteed in the contract), loans and repayments of policy loans are part of fulfillment cash flows. If future policy loans are initiated within the contract boundary, expected future loans and repayments as well as interest accrued on outstanding loans are also a part of the fulfillment cash flows.

2.13. How are premiums prepaid with interest accretion treated?

Prepaid premiums are treated the same as premiums paid at their due date. They are part of the cash inflows and the frequency and effect of their occurrence is included as part of future cash flows. In some cases, there is an agreement that the insurer grants a rebate on prepaid premiums in the form of interest accreted. If this agreement is a component of the insurance contract and not separated as a distinct investment component, the rebate is considered in measurement and treated as an adjustment to premium as per paragraph B65(a).

IFRS 17 does not directly address the issue of recognition of prepaid premiums but does require that liabilities reflect paid premiums not premiums due. In the same way as insurance acquisition cash flows arising before recognising the group of insurance
contracts are an asset according to paragraph 27, liabilities arising from prepaid premiums might be recognised but not necessarily as part of the cash flows.

2.14. How are extra premiums paid for substandard risks included?

Extra premiums for substandard risks are treated identically to other premiums. It is, moreover, important that expectations for the related future benefits are estimated on the basis of the correspondingly higher risk, so as to be consistent with the extra premiums. Actuaries might also consider whether the statistical knowledge available about the higher risk provides an adequate basis from which to develop an appropriate estimate that deviates from the extra premium determined. Similar considerations apply for premium rebates for risks better than standard.

Outflows

2.15. What are examples of outflows included in future cash flows?

Benefit payments, directly related expenses and similar items are the important items included in cash outflows.

2.16. What kind of data is used to estimate future cash outflows?

Paragraph B41 requires assumptions to be based on information including, importantly, the entity's own experience to the extent it is available, supportable and credible. The results arising from this data may be adjusted if there is reason to believe that historical trends will not continue in the future or if other influences may affect them. If internal data is not available, either in whole or in part, then industry or other available data, e.g., population data, may be used as a basis for the assumptions. In general, an entity's experience will be analysed for this purpose using an internal experience study.

Paragraph 33 (a) and B37 set limits on the effort required to collect the statistical basis of determining the assumptions. In general, information used should be reasonable, supportable and obtainable without undue cost or effort. Information available from the insurer's own information system, e.g., internal experience studies, and other sources used for pricing is considered available without undue cost or effort.

2.17. How are available inputs from financial markets and from other external sources applied to cash flow estimates?

If, for example, a portfolio has new elements on which the entity has no or limited experience, external inputs, such as industry experience, might be used. Available inputs from financial markets and from other external sources may not, however, represent characteristics of the cash flows of a certain portfolio; if that is the case, the entity's estimate or an adjustment to financial market information may be needed. As the entity obtains sufficiently robust experience of its own, it may consider supplementing the external data with it or eventually substituting its own experience.
2.18. What methods are appropriate to estimate future cash flows that might be dependent on market variables?

Stochastic projections (see IAA monograph on Stochastic Modeling) are allowed but are not necessarily required. They are, though, more likely to be needed for skewed risks than risks with symmetrical distributions. Stochastic methods will more likely be used to develop estimates of a risk adjustment (see IAA Monograph: Risk Adjustments under IFRS 17) or interest rates dependent cash flows than the usual mean estimate of common benefits. IFRS 17 refers to using, but does not require, stochastic modelling regarding cash flows that are asset-return sensitive (paragraph B48) and also if cash flows reflect a series of interrelated options (see paragraph B39 and paragraph B28 of IFRS 13 about the extent of such modelling needed).

In most cases, interest assumptions for stochastic models will be “risk-neutral” rather than “real world”.

2.19. What needs to be considered in estimating policyholder behaviour (e.g., surrender rights, options to convert to other types of contracts if such an option exists in a contract e.g., between a term and whole life contract)?

The basis for the expected value is the entity’s estimate of future expected behavior (based on experience and judgement), not necessarily rational financial behaviour (see B62). Experience might cover only a very limited range of circumstances as incurred up to the present. Accordingly, for a wide variety of possible future circumstances, no past experience may be available. In filling that gap, the actuary may wish to consider whether the chosen assumptions have a significant effect on the outcome compared with the outcome resulting from assuming that the behavior would be in line with past experience even in changed circumstances. If the difference is relevant, the actuary may consider if and how the experience needs to be adjusted to reflect expected future conditions (paragraph B41(c)). Risks from such assumptions are to be considered in the risk adjustment to the extent they are non-financial risk, depending on the nature of the risk. The expected value considers both advantageous and disadvantageous behavior of policyholders.

One of the considerations when setting assumptions is the possible effects of policyholder anti-selection. In certain circumstances policyholder behavior will depend on financial assumptions. In such situations, it may be important that those policyholder behavior assumptions be consistent with the interest rate assumptions being used. This may be true whether or not a stochastic approach is used.

Internal Costs

2.20. What methods are appropriate to estimate expected future internally incurred costs?

Estimates of future management costs will usually make use of any forecasts the entity makes including budgets and business plans. Those future unit costs will usually anticipate
inflation. It is also appropriate to allow for expected future economies (or diseconomies) of scale, consistent with the likelihood of these scenarios and unbiased mean.

Future unit costs will also consider the likelihood of the entity being measured as a going concern. Unit costs may therefore need to reflect a reasonable development of future new business, if appropriate, in deriving an unbiased estimate of the mean.

2.21. How are administration costs that are paid or expected to be paid prior or subsequent to contractual due date handled?

The proper measurement is based on the expected actual payment date, not the due date, and allows for any consequences of early or late payment (e.g. pre-paid or annualised commissions, interest accreted, penalties charged). If it can be shown, however, that there is no material difference between the actual and due dates, the measurement could be based on due dates. Caution needs to be taken to ensure consistency with the accounting treatment, to avoid double counting or omission.

2.22. Which cash flows other than claims payments and contractual services may be considered?

The key guidance for differentiating cash flows other than claims payments and other contractual services is the exclusion of general overhead costs in paragraph B66 (d) if they “cannot be directly attributed to the portfolio of insurance contracts that contain the contract”. See B65(i), on the other hand, for examples of some overheads that are included in estimated future cash flows. Those general overhead costs are not included in the estimate of future cash flows of IFRS 17 and are accordingly subject to authoritative guidance in other IFRSs determining their recognition, measurement, presentation and disclosures. This Chapter does not discuss such items.

The reference to “directly attributable” is a generally used phrase in IFRSs and the entity might have previously adopted interpretations of that term in its accounting policies. This Chapter does not discuss further the accounting meaning of this phrase. The accounting interpretation of this phrase might, however, result in the need to choose the partition of the business into Portfolios of Insurance Contracts (PIC) suitably to allow an adequate split of currently incurred and future expected cost between those “directly attributable” to a PIC and general overhead that is not considered in measurement and presentation of insurance contracts.

After identifying those internal costs that can be directly attributed to portfolios of insurance contracts, those costs might be differentiated regarding their function in fulfilling the insurance contracts. IFRS 17 distinguishes insurance acquisition cash flows from other internal costs. IFRS 17 is silent regarding how to accomplish this separation, which might be seen as an indication that normal cost accounting approaches, particularly key allocations between functions are appropriate.
In summary, the identification of costs considered in measurement might be split in three separate steps:

1) Exclude costs that are not directly attributable to a portfolio of insurance contracts (B66 d)).

2) Allocate the remaining costs to functions, i.e., insurance acquisition cash flows, servicing contracts during their coverage period and settling claims based on normal cost accounting principles (B65 (e), (f), (h) and (l)).

3) Allocate the identified costs per function to each group of insurance contracts “using methods that are systematic and rational, and are consistently applied to all costs that have similar characteristics” (B65 (l)).

2.23. What are insurance acquisition cash flows?

Insurance acquisition cash flows are defined (see Appendix A of IFRS 17) as “the costs of selling, underwriting and starting a group of insurance contracts that are directly attributable to the portfolio of insurance contracts to which the group belongs. Such cash flows include cash flows that are not directly attributable to individual contracts or group of insurance contracts within the portfolio.” These include direct payments, such as commissions, underwriting costs, and other costs of contract issue specific to a particular contract, but also include such costs incurred for a portfolio of contracts. They may not include allocation of some overhead expenses.

To differentiate acquisition costs from other costs, particularly contract administration costs, the contract boundary might be of relevance. If a payment is contingent on persistency beyond the contract boundary, it might be seen as an acquisition cost outside the contract boundary. Therefore, those costs are not included in the cash flows of the existing contract. In that case, the item is recognised as an expense only when the new contract becomes in force. If the payment is contingent only on persistency within the contract boundary it is generally an administration cost.

2.24. How are insurance acquisition cash flows considered if paid prior to initial recognition of the related group of insurance contracts?

Insurance acquisition cash flows incurred prior to initial recognition are reflected as paid and capitalised until the related group of insurance contracts is issued. An exception to this is for contracts using the PAA that have a duration of 12 months or less. Such contracts may choose to recognise acquisition costs as expenses when incurred (Paragraph 59).

2.25. How are insurance acquisition cash flows considered if paid in a reporting period (in the same year, in a subsequent year) after initial measurement (e.g., renewal commissions or asset-based commissions)?

Insurance acquisition cash flows incurred after the initial sale, are reflected in the same way as other future costs, regardless of the year in which they are paid. That is, they are included in the contract’s estimated future cash flows on a probabilistic basis. Therefore, for example, if the payment of the commission is dependent on the policy continuing within the contract boundary, the probability of lapsation is reflected.
In this sense, they are considered to be directly attributable expenses. The question of whether they are acquisition costs or direct administration costs is moot.

2.26. If agent / agency compensation is contingent upon agent / agency survival, how might those expenses be reflected (and if so, how might agent / agency turnover be considered)?

These expenses are usually included in estimated future cash flows in the same way as for other contingent cash flows, e.g. claim handling costs. Hence if agent / agency turnover materially affects expected cash flows, this needs to be considered in determining estimated future cash flows whether the expenses are for acquisition or maintenance of the contract.

2.27. What are some examples of expenses that are or are not insurance acquisition cash flows?

Insurance acquisition cash flows include, but are not limited to:

- Commissions to sales personnel
- Payments to managers of agencies or brokerages based on a percentage of commissions or other measurements of sales
- Underwriting costs
- Contract set up expenses

The following might not be considered insurance acquisition cash flows:

- Payments to managers of agencies or brokerages not based directly on sales
- Payments to managers of agencies or brokerages based on policy persistency
- Premium and commission processing costs

Other Cash Flow Issues

2.28. Are any taxes included in cash flows?

See B65. All transaction-based taxes (such as premium taxes, value added taxes and goods and services taxes) and levies (such as fire service levies and guarantee fund assessments) are included in cash flows. Wage based taxes, referred to as payroll taxes, social security taxes and similar items, are also included to the extent the wages they are based on are included. Also included would be any taxes paid on behalf of the policyholder. If the impact of certain of these taxes is only the small difference of the time value of the incoming and outgoing cash flows, those impacts could usually be ignored based on materiality considerations but noted in disclosures.

Income taxes and other similar taxes (e.g., a tax based on Investment Income and Expenses) levied on the entire entity are not included as a cash flow in contract measurement even if they are reflected in benefits paid to policyholders unless paid in a fiduciary capacity on behalf of the policyholder.
2.29. Are there any special considerations for discretionary or voluntary payments to policyholders?

For policyholder bonuses or dividends see chapter 8 on Contracts with Participating Features and Other Variable Features. Similar items on non-participating contracts (e.g., excess interest payments) will generally be measured in the same way they would be measured on a participating contract. For other discretionary cash flows of the entity, including any fair dealing in determining claims payable, whether their consequences are within or beyond the contract boundary needs to be considered. If they are with respect to services provided within the contract boundary, they may also be measured at the expected value. Otherwise, they are generally not included.

2.30. How are policyholder dividends or bonuses projected for traditional participating contracts?

See Chapter 8 on Contracts with Participating Features and Other Variable Features.

2.31. How are delayed benefits, benefits which are expected never to be paid, or events that create rights contingent on future events (e.g., annuities to persons under third party liability, or joint life) accounted for?

These benefits are normally included in the same way as other benefits, at their expected value. This may be different from previous accounting structures that, in some instances, measure such benefits only after they are elected.

2.32. How are interest credits paid to policyholders projected?

See Chapter 8 covering Contracts with Participating Features and Other Variable Features.

2.33. Where is there available guidance for estimating inflation and its effects on inflation-sensitive benefits, claims and expenses?

Paragraph B128 (b) provides guidance on when inflation risk is to be seen as non-financial risk. When seen as financial risk, paragraph B51 provides as an example a reference to observed market interest rates. A range of statistics is available in different countries. General living cost or wage indices might be useful for many cash flows, but building, medical and other insurance relevant expenses may also have their own indices or may be responsive to specific factors other than general inflation. In addition, as inflation applies to the entity's internal expenses, the relative change in productivity and changes in the number of units can also influence trends in unit expenses. As long as observations can be made regarding (neutral) expected values of inflation in market prices for the specific cash flow to be measured, those observations have priority compared with the entity's expectations.

2.34. How can cash flows on blocks of business with no prior experience or no relevant experience (e.g., new line of business for entity, mortality past age 90 or coverage durations longer than the product has been issued) be estimated?

The best available relevant experience, both any related internal experience and any available data from the industry, may be considered. This is likely to be supplemented by documented judgment.
2.35. How might cash flows on contracts covering multiple perils be developed?

This depends on the nature of the contract and the nature of the peril.

For example, many general insurance contracts cover standard combinations of perils. In such cases, the standard combination might be treated as a single peril.

If the perils are fully independent, then simple addition can be used; however, if the data for one peril is not sufficient for a reliable estimate, then estimating cash flows by peril may not be recommended.

Interdependent perils (e.g., joint life, first death) can be adjusted for the probabilities of co-incidence.

2.36. How might cash flows on a single contract with multiple insured items, particularly if there is an open number of insured items in the contract (e.g., a group life contract or a corporate auto contract) be adjusted for added or deducted insured items?

Where an additional premium is to be agreed for each additional insured item (e.g., group life, health or disability), estimates may be made on the basis of the insured items active at the measurement date, since the additional insured item is beyond the contract boundary before it is added.

Where a fixed premium is charged even if the number of insured items can change within the contract boundary, then an expected value approach is appropriate for estimating the number of insured items which will be covered within the contract boundary.

Changes in estimates

2.37. How often are estimates re-evaluated?

Estimates must be re-evaluated at every reporting date. In compliance with paragraph 33 (c) and B54-B60, the assumptions for estimating the cash flows also have to be re-evaluated at each reporting date. If there is no positive indication that anything relevant has changed, however, no change to an assumption is allowed.
Chapter 3 – Discount Rates

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality

3.A. What does this chapter address?

This chapter discusses practices related to interest rates, yield curves, discounting and replicating portfolios for insurance contracts as required by IFRS 17. First the general principles for discounting within IFRS 17 are discussed in questions 3.1-3.10. Discount rates used for cash flows that do not vary based on the returns on financial underlying items\(^8\) are discussed in questions 3.11–3.24. Discount rates for cash flows that do vary based on the returns on financial underlying items are discussed in questions 3.25-3.31. Discounting related to PAA is covered in questions 3.32-3.35 and locked-in discount rates are discussed in questions 3.36-3.41.

3.B. Which sections of IFRS 17 address this topic?

Paragraphs 36 and B72 – B85 provide guidance on this topic.

Related sections are paragraphs B44-B48 (on market variables) and paragraphs 87, 110-113 and B128-B136 (on insurance finance income and expenses).

BC 19, BC 185 – BC 205, and BC 212 also provides background on the subject.

3.C. What other IAA documents are relevant to this topic?

---

\(^8\) The standard defines underlying items which might include both financial and non-financial elements. As only financial underlying items are relevant for the discount rate, only financial underlying items will be referred to in this section.
General topics

3.1. What are the general principles related to discounting within IFRS 17?

An amount payable today has a different present value from that of the same amount payable in the future. In other words, money has a time value. Discount rates are used to adjust cash flows to reflect the time value of money. The following general principles underpin the discounting guidance within IFRS 17.

Principle 1: Estimates of future cash flows are adjusted for the time value of money and the financial risks related to those cash flows, to the extent that the financial risks are not included in the estimates of cash flows (paragraph 36).

Principle 2: Discount rates are reflective of whether the cash flows vary based on the returns on any financial underlying items (paragraph B74).

- For some insurance contracts, e.g., most general insurance and non-participating traditional term life or non-participating whole life insurance, the cash flows are not dependent on financial underlying items. IFRS 17 refers to these products as having cash flows that do not vary based on the returns on any financial underlying items. The discounting for these cash flows is discussed in questions 3.11-3.26.

- Other insurance contracts, e.g., unit-linked universal life insurance and variable annuities, typically have cash flows that are dependent on financial underlying items. IFRS 17 refers to these products as having cash flows that vary based on the returns of any financial underlying items. The discounting for these cash flows is discussed in questions 3.25-3.31.

- Based on the definitions in the standard, the distinction between cash flows that do vary based on the returns on financial underlying items and cash flows that do not vary based on financial underlying items is not equal to the distinction between insurance contracts with direct participation features and insurance contracts without direct participation features. This is further explained in question 3.9.

Principle 3: The discount rates applied to the estimates of the future cash flows reflect the characteristics of the cash flows and the liquidity characteristics of the insurance contracts (see paragraph 36a).

- The discount rates applicable to fully liquid instruments (the “risk-free curve”) are discussed in question 3.12;

- The liquidity characteristics of insurance contracts are discussed in questions 3.14-3.17.
**Principle 4:** The discount rates are consistent with observable market prices, if any, for financial instruments with cash flows whose characteristics are consistent with those of the insurance contracts and they shall exclude the effect of factors that influence such observable market prices but do not affect the future cash flows of the insurance contracts (paragraphs 36b and 36c).

- The concept of a reference portfolio is discussed in question 3.12
- It may be possible to determine the discount rates for a portfolio of insurance contracts by identifying a replicating portfolio. This is discussed in question 3.29.

**Principle 5:** Assumptions for the estimates of discount rates are consistent with assumptions for other estimates used to measure insurance contracts to avoid double counting or omissions (paragraph B74). For example, if nominal cash flows include the effect of inflation they are discounted at rates that include the effect of inflation. Similarly, when discounting cash flows that vary with financial underlying items, the financial return assumptions used to estimate future cash flows and the discount rates used are aligned (see questions 3.25 and further)

### 3.2. For which purposes are discount rates required?

Paragraph B72 lists the purposes for which discount rates are required.

<table>
<thead>
<tr>
<th>An entity shall use the following discount rates in applying IFRS 17:</th>
<th>Discussed in questions</th>
</tr>
</thead>
<tbody>
<tr>
<td>a) to measure the fulfilment cash flows – current discount rates applying paragraph 36.</td>
<td>3.11-3.31</td>
</tr>
<tr>
<td>b) to determine the interest to accrete on the contractual service margin [...] for insurance contracts without direct participation features – discount rates determined at the date of initial recognition [...].</td>
<td>3.36</td>

<tr>
<td>e) If an entity chooses to disaggregate insurance finance income or expenses between profit or loss and other comprehensive income (IFRS 17.88), to determine the amount of the insurance finance income or expenses included in profit or loss:</td>
<td></td>
</tr>
</tbody>
</table>
(i) for groups of insurance contracts for which changes in assumptions that relate to financial risk do not have a substantial effect on the amounts paid to policyholders [...] – discount rates determined at the date of initial recognition [..];

(ii) for groups of insurance contracts for which changes in assumptions that relate to financial risk have a substantial effect on the amounts paid to policyholders [...] – discount rates that allocate the remaining revised expected finance income or expense [...] at a constant rate; and

(iii) for groups of contracts applying the premium allocation approach [...] – discount rates determined at the date of the incurred claim [..].

3.3. How are liquid risk-free rates determined in the context of IFRS 17?

A liquid risk-free yield curve is discussed in paragraphs B80 and in BC193. It is the basis of the bottom-up approach which is discussed in question 3.13. The liquid risk-free curve may not be required in a purely top-down approach (which is discussed in question 3.18.)

IFRS 17 does not define a method to derive the liquid risk-free yield curve. Favourable characteristics for market quoted interest rates used in deriving a liquid risk-free yield curve might include those quoted interest rates:

- Being reliable and liquid;
- Containing no credit risk; and
- Having quoted / maturity dates for a wide range of terms/durations.

To set an entire curve, practitioners may, in some cases, consider using more than one security type or market index / reference rates to derive the overall curve. Thus, deriving the liquid risk-free curve may involve judgement.

Some options and considerations that might be applied are set out below9:

a. Government bond rates

Politically stable governments in economically developed countries are commonly believed to have a low probability of defaulting on their debts. This is because governments in such countries have taxing power and the ability to expand money supply (which is not the case for all governments). The rating of government bonds

---

9 Other publications on the subject could help the practitioner to derive such a curve (for example: (EIOPA, 2017), (IAA, 2013)).
can be used as an indicator as to whether the bonds of the specific government may be considered risk free.

In the situation of a currency union, a basket of government bonds with a high rating might be used. In the situation of a currency union, an individual government does not have the ability to expand the money supply which may cause credit risk. Also national governments can issue debt. If credit risk is present, an approach that estimates the credit risk component so that it might be removed is described in question 3.19 below.

Apart from the credit risk, the available maturities and the liquidity of the government debt market varies between governments. These may be factors when choosing between government bonds and alternative bases for the risk-free curve development.

b. Swap Curve

In many markets swap curves are observable and available for a range of terms. In some cases, they are more liquid and available for a greater range of terms than government securities.

Swaps are often used as instrument for replicating and hedging interest rate risk arising from derivative assets which makes them a natural reference to derive risk-free interest rates. Furthermore, swap contracts are typically collateralised and there is no risk on the principal value associated with the swap agreement, which substantially reduces the exposure to losses associated with a credit default event. For example, the EIOPA Solvency II approach uses Swap Rates for currencies with deep financial markets.

Quoted swap rates may have to be adjusted in order to reflect:

- The counterparty credit risk: A party who is receiving a fixed interest rate (i.e., fixed / quoted leg) from another party is likely to require a premium on top of the interest rate to compensate for the risk related to future interest payments on the fixed leg in excess of the floating leg. The “swap rate” will include an allowance for credit risk and an adjustment would be required, taking into account collateralisation requirements.

- The underlying reference security credit risk: If swap rates are based on the yield of an underlying reference security with material credit risk premiums these risk premiums would need to be removed to obtain a risk-free rate.

---

10 Note that the volatility adjustment is not compliant to IFRS 17.
Understanding the basis underlying quoted rates is important when choosing any adjustment in relation to counterparty risk. Similarly, understanding the underlying reference securities is important when choosing any adjustment for credit risk.

c. Corporate Bond Rates

Corporate bond rates are not risk free although in some jurisdictions, it may be the most widely traded market. Credit risks need to be considered in the context of corporate risks. Techniques that might be considered when using corporate bond rates are similar to those presented in question 3.19.

3.4. How can risk free rates be determined if there is no well-developed bond or swap market?

When, for a given currency, there is no well-developed bond or swap market other approaches may be considered. Two situations can be distinguished:

a. The local currency is pegged to another currency;

b. The local currency is not pegged to another currency.

The local currency is pegged to another currency

The suitability of this approach depends upon adequately allowing for any risks that the level of the peg may change. This risk causes a spread on rates in the local currency. Evaluating this risk may require particular care given that in these situations there may be a lack of forward exchange rate contracts which, if they were available, would be one source of a market observable measure of the risk of the peg changing. Observed deviations in the past from the pegging policy may be an indicator for a correction on the targeted difference.

The local currency is not pegged to another currency

Short nominal rates may be derived from the rate the central bank offers for deposits. For long durations, one might consider using a global real rate plus a compensation for the inflation the local central bank is targeting. The targeted inflation may be adjusted using expert judgement if for example the risk of higher inflation on the long run is considered realistic. Observed differences in the past between the targeted inflation and the realised inflation may be an indicator for the need of an adjustment. In the globalised economy differences between real rates in developed countries have declined. See graph below. However, it might be appropriate to consider whether that narrowing will remain. For the estimation of a global real rate, an option is to use a basket of high rated government bonds or swap rates. It is a matter of judgment how much weight is put to each country. One might use for example the GDP as a weight.

Local real rates may deviate from the global real rate if there is a strong demand for loans when a country is in a developing phase. An estimation of a difference between the local risk free real rate and the global risk free real rate in the long run is difficult. This is a matter
of judgement. Estimation of the inflation in the long run could be an even a bigger challenge. It comes largely down to expert judgement.

If quotes for forward exchange rate contracts are available, this information can be used to convert other risk-free rates in other currencies to the rate for the local currency.

3.5. How is inflation reflected in discount rates?

Paragraph B74 states that nominal cash flows (i.e., those that include the effect of inflation) shall be discounted at rates that include the effect of inflation. Real cash flows (i.e., those that exclude the effect of inflation) shall be discounted at rates that exclude the effect of inflation.

Cash flows subject to inflation may therefore either

(i) be projected including the effects of inflation and discounted with a nominal rate or
(ii) be projected without inflation and discounted with real rates.

There are several potential methods that may be suitable for deriving inflation and/or real interest rate expectations. Some potential methods and aspects to consider in their application are discussed below. The considerations listed may not be exhaustive.

- **Market based approaches**
  - Estimating inflation by taking the difference between nominal bond yields and inflation-linked bonds. This method requires limited judgement where the issuer / credit risk of the bonds is the same (otherwise judgement / subjectivity is involved in
making further adjustments for differences in yield due to credit risk). More considerations may be required because in some markets, while the nominal bond market is considered reliable and well-functioning, the index-linked bond yields may be biased because of smaller volumes on issue and other supply/demand factors. This would then bias the derived estimate of inflation.

- Inflation swaps/other market instruments – investment banks or other traders may offer contracts that provide exposure to future inflation. These may not be common, causing possible biases given limited availability. Where such trades occur, the prices may not be readily and publicly available. Nonetheless, where such information is available it may assist by providing insight into market information on inflation estimates.

- **Publicly available estimates**

  - Central bank targets for inflation.

  - Forecasts of economic commentators and/or government bodies.

  - Views of a long-term real risk-free rate. This is discussed further in question 3.21. This may assist with setting the long-term inflation estimate but is likely to be less helpful in setting short-term estimates.

Publicly available estimates may not be the same as the results of market-based approaches or may not align with realised inflation over time for the cash flows. If public estimates and market-based approaches are not similar over a given time horizon, then an evaluation of the causes of difference may be useful. The appropriate adjustments will be based on the cause of the differences.

Potential causes of differences may be as follows:

- The corresponding central banks may not always achieve their target which may extend to different economic expectations over the long run.

- Market based estimates can be biased due to limited volume of transactions available.

Some cash flows of an insurance contract may depend on a different inflation index to a commonly available index such as the consumer price index (CPI) and may be linked instead to salary inflation which, over time, is likely to differ from CPI. Or for example, the expenses of an insurance company may be expected to grow at a different pace than the CPI. Also, the insured amount may depend on an inflation index that is not equal to the CPI. If this is the case, the appropriate inflation expectation would need to be used in the measurement, or in accordance with paragraph B74d, where the inflation component is excluded from both the cash flows and the discount rate. Whilst projected CPI (in this example) would be considered part of financial risk for measurement purposes, where
different inflation assumptions are used for expenses or other cash flows, the extent to which these inflation assumptions differ could be considered as part of non-financial risk, with implications for the determination of the risk adjustment.

3.6. Is ‘own credit risk’ reflected in discount rates under IFRS 17?

No, non-performance risk (defined in IFRS 13 Fair Value Measurement) related to the entity that has issued the insurance contract, as ‘own credit risk’, is not reflected (see paragraph 31) in the discount rates.

Non-performance risk with respect to reinsurers is accounted for in the valuation of reinsurance contracts held however.

3.7. Are investment administration expenses reflected in discount rates (or cash flows) under IFRS 17?

There is no direct guidance in the standard about this topic, but some information can be found in BC201 which states:

- to the extent that the cash flows from underlying items affect the cash flows that arise from the liability, the appropriate discount rate should reflect the dependence on the underlying items; and

- to the extent that the cash flows are expected not to vary with returns on underlying items, the appropriate discount rate should exclude any factors that influence the underlying items that are irrelevant to the contracts. [...] Thus, the discount rate should not capture all of the characteristics of those assets, even if the entity views those assets as backing those contracts.

One view is that the IASB intended that only investment administration expenses that affect the return of the underlying items might be reflected in the discount rate or cash flows, but not both to avoid double counting. Investment administration expenses related to the actual investments of the company, under any other circumstances, might not be captured in the discount rate (nor the cash flow). They are irrelevant to the insurance contract.

3.8. How are yield curves updated?

Paragraph 36 requires that the discount rate be consistent with observable current market prices (if any) for financial instruments with cash flows whose characteristics are consistent with those of the insurance contracts, in terms of, for example, timing, currency and liquidity. Observable current market prices correspond to the value of market instruments at the reporting date and are therefore updated at each subsequent reporting period to remain current. Unobservable inputs for which estimation techniques are necessary are developed using the best information available in the circumstances. These might be updated less frequently than every reporting period. All financial assumptions used to derive yield curves are expected to be appropriate at the valuation date.
3.9. Do contracts with cash flows that vary based on the returns on financial underlying items meet the definition of insurance contracts with direct participation features and vice versa?

Contracts with cash flows that vary based on the returns on financial underlying items may meet the definition of insurance contracts with direct participation features in Appendix A, but this not always the case.

Note that all contracts with direct participation features, by definition, have contractual terms that specify that the policyholder participates in a share of a clearly identified pool of underlying items. These underlying items are typically financial in nature and the contracts have cash flows that vary based on the returns on financial underlying items.

For contracts that do not meet the definition in Appendix A, the GMA is used or the PAA, while for ‘direct participating’ contracts, the VFA is used. In this chapter, we distinguish between “cash flows that do not vary based on the returns on any financial underlying items” and “cash flows that do vary based on the returns on any financial underlying items” in order to describe the techniques deriving appropriate discount rates. A further explanation of participation features and the description of underlying items can be found in Chapter 7 “Contracts with participation features and other variable cash flows”.

3.10. Can an equivalent (constant) discount rate be used in IFRS 17, instead of a discount curve?

A common actuarial practice is to translate a discount curve into an equivalent discount rate by solving for a constant rate such that, for the pattern of cash flows, the present value produced by using the constant rate equates the present value produced by using the discount curve. This translation is highly dependent on the pattern of cash flows. For the same (non-flat) discount curve, different constant discount rates would result were the pattern of cash flows different. Reasons to conduct this translation include for data storage simplification and calculation ease.

Paragraph 36 requires the discount rates used to reflect the time value of money, the characteristics of the cash flows and the liquidity characteristics of the insurance contracts. If the equivalent discount rate achieves the above, then it is more likely to comply with the standard. However, in using this method, current and future purposes of this method for which the single equivalent discount rate will be used, may need to be reflected on.

As discussed in question 3.2 there are different purposes for discount rates in IFRS 17. Many practitioners believe that to calculate the fulfilment cash flows the use of a discount curve is required to be consistent with paragraph 36. In this context, a single equivalent discount rate might provide information but is unlikely to have broader uses. See question 3.39 for a discussion of equivalent constant discount rates in the context of the locked-in curve.
Cash flows that do not vary based on the returns on any financial underlying items

3.11. How are cash flows, that do not vary based on the returns on any financial underlying items, discounted?

Paragraphs B80 to B85 establish two methods to determine rates for discounting cash flows that do not vary based on the returns of financial underlying items, the bottom-up approach (paragraph B80) and the top-down approach (paragraphs B81 to B85).

Both approaches are briefly discussed in BC196: ... (a) a ‘bottom-up’ approach based on highly liquid, high-quality bonds, adjusted to include a premium for the illiquidity. (b) a ‘top-down’ approach based on the expected returns of a reference portfolio, adjusted to eliminate factors that are not relevant to the liability, for example market and credit risk. The Board expects a reference portfolio will typically have liquidity characteristics closer to the liquidity characteristics of the group of insurance contracts than highly liquid, high-quality bonds. Because of the difficulty in assessing liquidity premiums, the Board decided that in applying a top-down approach an entity need not make an adjustment for any remaining differences in liquidity characteristics between the reference portfolio and the insurance contracts.

Following the approach set out in BC196, a reference portfolio would need to be defined if using the top-down approach. For the bottom-up approach, an illiquidity premium has to be estimated, which may also require a reference portfolio.

3.12. What is a reference portfolio?

IFRS 17 has no specific requirements for the reference portfolio. It could be based on actual assets held by the company or on a theoretical portfolio of assets. However, the better the reference portfolio reflects the characteristics (e.g., liquidity) of the cash flows for which the discount rate is being developed, the smaller adjustments are likely to be needed in the discount rate. When starting with the actual assets held by the company, an assessment on whether the portfolio still reflects the characteristics of the cash flows whenever the investment strategy changes materially may be done.

Factors that may differ between the characteristics of a reference portfolio and that of a portfolio of insurance contracts include, but are not limited to:

i. **Investment risks**: Investment risk can consist of credit risk, market risk, and other price risks that are inherent in the reference portfolio and are not inherent in the insurance contracts. Methods used to estimate these elements are discussed in question 3.19 (credit risk) and question 3.20 (market and other risks);

ii. **Timing**: The timing of cash flows within the reference portfolio may not be the same as that of the liability contracts. Adjustments may be considered, based on observable assets traded in active markets or on estimation techniques if the market is not active or no market exists. Estimation techniques for long duration interest rate are discussed in question 3.23;
iii. Currency: The reference portfolio of assets may contain assets that are in a
different currency than the liabilities. One approach to adjust for the different
currencies might be currency swaps.

NB a reference portfolio is different from a replicating portfolio (Paragraph B46) which
exactly matches cash flows of the contract liability in amount, timing and uncertainty, for
all scenarios.

3.13. How does the bottom-up approach work?

The bottom-up approach is described in paragraph B80 as:

a) liquid risk-free yield curve;

b) adjusted to reflect the liquidity characteristics of the insurance contracts.

3.14. What are the liquidity characteristics of insurance contracts?

Paragraph 36 states that the discount rates applied should reflect the liquidity
characteristics of the insurance contracts.

In order to understand the nature of insurance contract liquidity characteristics one may
consider the liquidity characteristics of other financial instruments: in the context of fixed
income financial instruments, liquidity is the ability to convert the asset into cash or
extinguish the liability on demand. The liquidity arises from either call or put options
embedded into the instrument or the marketability of the instrument.

BC193 specifically draws the parallel between insurance contracts and fixed income
financial instruments and suggests that liquidity characteristics of insurance contracts be
viewed from the perspective of the features embedded within the contract. This view is also
echoed in the IAA Discount Rate Monograph which, on page 38 of section IV, states: the
liquidity of a liability is a function of the basic contract provisions, and especially any options
that might exist for the policyholder that would impact the uncertainty regarding the amount
and timing of payments.

This answer addresses the liquidity characteristics of insurance contracts from the
perspective of the contract's features. Some practitioners ask if the liquidity characteristics
of insurance contracts should be assessed from the insurer's perspective. The motivation
of this view is BC194 which suggests that the motivation of including a liquidity premium is
the entity's ability, or lack thereof, to sell / put the contract. The focus of IFRS 17 in general
is on the insurance contract features and as such this answer explores liquidity from the
perspective of the contract's features.

Note that this answer focuses on qualitative assessments of insurance contract liquidity.
See response to question 3.15 for a discussion on the quantitative assessment of illiquidity
premium.
Contract features that may influence the liquidity of an insurance contract include:

- **Exit costs**: all else being equal, a contract with exit costs (e.g., surrender charges / penalties) is likely to be more illiquid than one without. Note exit is contemplated as voluntary exit / cancellation of contract and occurrence of the insured event is not considered a contract exit, as contemplated in this response.

- **Inherent value / value build-up**: If a contract’s pricing / construction is such that there is negligible / no inherent value then, other than any exit costs, it is likely to be considered liquid. If on exit of a contract there is:
  - little inherent value in the contract and there are no costs to exit the contract then the contract could be considered to be liquid;
  - little inherent value in the contract and there are costs to exit the contract then the contract could be considered to be illiquid.

For example, yearly renewable general insurance contracts, whose design builds negligible value and are without exit costs, are likely to be considered liquid.

For contracts with no cash value, increasing risk and level premium payment, longer contract boundaries are potentially less liquid than contracts with shorter boundaries as the extended boundary potentially leads to greater inherent value / value build-up. To illustrate this a twenty-year term insurance contract could be viewed as less liquid than a two year term insurance contract.

- **Exit value**: all else being equal, a contract where upon exit all / a large part of the value build-up is paid out is more liquid than one that pays out none or a small part of the value build-up. If on exit of a contract there is:
  - value in the contract and the policyholder receives all / a large part of the value of the contract, then the contract may be considered to be liquid;
  - value in the contract and the policyholder receives no / a small part of the value of the contract, then the contract may be considered to be illiquid.

Liability for incurred claims might be considered illiquid as there is no potential avenue for the policyholder to obtain the exit value yet there is tangible inherent value (else a claim would not have been made.)

The repayment of annual premiums on exit of a contract are not considered by many practitioners to be an exit value payment as they are a repayment of prepaid premiums and not of the value build-up. In such cases, contracts with annual premiums would have similar liquidity as those with monthly premiums. Forfeiture, though, of annual premiums on exit when no penalty would have existed for monthly premium policyholders, may influence liquidity differences.
The liquidity of an insurance contract likely varies over time. For example:

- The twenty-year term insurance example could be considered to be more liquid in the contract’s first year than in the contract’s fifteenth year based on the growing value of initial underwriting no longer being recent.
- The contract with high cash surrender value could be viewed as less liquid in the contract’s tenth year than in the contract’s fifteenth year based on the exit value receivable.

For operational reasons it is conceivable that an overall assessment / categorisation be made consistent with the response in question 3.16

One contract feature that is unlikely to affect the liquidity of insurance contracts is the predictability (or lack thereof) of the contract’s cash flows. The risk adjustment for non-financial risk reflects the compensation that the entity requires for bearing the uncertainty about the amount and timing of the cash flows that arises from non-financial risk.

An environmental feature that is unlikely to influence the liquidity of a contract is the potential for viatical settlements. Viaticals provide policyholders, who may not place a high value on any remaining death benefits, with a payment from a third party for their contract where no or little exit value might exist as part of the contract feature. However, since the contract features remain unchanged and assuming that the insurer’s required payment is only made upon occurrence of the insured event, the existence and depth of a viatical market would seem to affect the calculation of probability weighted cash flows and would not seem to affect the contract’s liquidity.

3.15. How can the liquidity characteristics of insurance contracts be quantified?

The adjustment to reflect the liquidity characteristics of the insurance contracts has been broadly termed the illiquidity premium. Highly liquid insurance contracts would have a low (or even no) illiquidity premium while very illiquid contracts would have a higher illiquidity premium.

Data relating to illiquidity premium of insurance contracts is generally not directly available in the market. Looking beyond insurance contracts, market prices for liabilities where the issuer of debt has the possibility to redeem the debt early are also very limited.

A theoretical approach to determine the illiquidity premium is to assess possible replicating portfolios. This is discussed in question 3.29. Some practical approaches of estimating illiquidity premiums for insurance contracts include:

- Using a reference portfolio and determining its illiquidity premium using top-down techniques (see questions 3.18 to 3.20); and
- Comparing yields on illiquid and liquid assets, both with the same or similar degree of credit risk. The commonality in these approaches is that the instruments are
considered to have the same degree of credit risk and as such the spread difference would be largely attributable to liquidity. For example:

- Covered vs risk-free bonds: Covered bonds are illiquid bonds which are backed by collateral and as such, are considered safe;

- Public and private debt issued by the same issuer; and

- Highly liquid and less liquid mortgage backed securities.

If the asset portfolio used in estimation is more liquid than the insurance contracts being considered, then additional adjustments may be needed. The illiquidity premium of insurance contracts may be different from market assets. However, this is dependent on the contract itself.

What follows is an example of a simple method used to relate the illiquidity premium of insurance contracts to the asset portfolios:

Assume liability illiquidity premium = r * asset portfolio illiquidity premium + constant illiquidity premium difference where the constant term and multiplicative factor (r) is set based on either judgement or data if any is available. In the selection of the factor differing market environments may be taken into consideration. For example, using a high multiplicative factor (r) and a constant = 0 may not produce a convincing result during a credit crisis. It would be difficult to justify insurance contracts having a higher illiquidity premium than the return on assets available for investment earning the illiquidity premium. This, however, is not a directly relevant factor in setting the illiquidity premium level.

The above approach is based on a top-down approach. For those using bottom-up there may be a discernible relationship between the level of the illiquidity premium and other market data such as the level of risk-free rates and / or the level of credit spreads. For example, there may be a different illiquidity premium in a 10% rate environment than in a 5% environment. However, if analysis showed the same level of credit spreads in these disparate environments then the level of illiquidity premiums in these environments might be the same.

Little is known about the term structure of illiquidity premium in current research and it is expected to be a function of the modelling approach selected. One reference that discusses the term structure of the illiquidity premium is (Kempf, 2011). Note that if the liquidity characteristics vary over time, then the implicit illiquidity premium in the discount rate would also be expected to vary over time. However, materiality / modelling and operational considerations may also influence approach choice.

An important caveat in setting the illiquidity premium is discussed in paragraph B90 which states the discount rates should not include any implicit adjustments for non-financial risk.
The illiquidity premium corresponds to the estimate reflected in the future cash flows while uncertainty attributable to non-financial risk is reflected in the risk adjustment for non-financial risks. In calculating these values, paragraph B90 states that double counting should be avoided.

3.16. Are different products expected to have different illiquidity premiums?

Insurance contracts exhibiting different features may have different exit costs, inherent value and/or exit value. As such, products are expected to have different illiquidity premiums. Products within the same portfolio, however, may have similar illiquidity premiums / characteristics since they are similar risks. An entity may elect to use a single average illiquidity term structure across products within a given portfolio.

3.17. If a contract is reinsured, would the direct issuer use the same illiquidity premium when valuing the direct and the ceded contract?

NB - the illiquidity premium from the reinsurer’s perspective is not in scope for this question as it would be determined in accordance with the previous questions.

Paragraph 63 states that “the entity shall use consistent assumptions to measure the estimates of the present value of the future cash flows for the group of reinsurance contracts held and the estimates of the present value of the future cash flows for the group(s) of underlying insurance contracts”.

This consistency is required to the extent that both the underlying contracts and the reinsurance contracts share the same characteristics. This requirement does not necessarily permit the entity to use the same assumptions used for measuring the underlying contracts when measuring the reinsurance contracts if those assumptions are not valid for the terms of the reinsurance contracts held. If different assumptions apply for the reinsurance contract, the entity uses those different assumptions when measuring that contract.

For example, consider a coinsurance contract where a predetermined proportion of all the direct contract characteristics are transferred to the reinsurer. In that particular case, one could expect the direct and ceded insurance contracts to exactly have the same illiquidity premium. On the other hand, consider a level premium term life insurance contract for which only mortality risk would be reinsured on a yearly renewable term basis. In this case, the direct and the reinsurance contracts have different characteristics and a different illiquidity premium would apply. Overall, in this example, the yearly renewable reinsurance contract would be expected to be more liquid than the level premium direct contract.

3.18. How does the top-down approach work?

An entity may determine appropriate discount rates for insurance contracts using a top-down approach (paragraph B81). Under this approach, discount rates are based on current market rates of return of a reference portfolio of assets which are adjusted to remove risk
characteristics embedded within the reference portfolio but that are not inherent in insurance contracts. These adjustments are discussed in questions 3.19 and 3.20.

IFRS 17 does not require that adjustments to the yield curve be made for residual differences in liquidity characteristics of the insurance contracts and the reference portfolio. Nonetheless, an entity may still adjust the yield curve for these differences, as discussed in questions 3.14-3.17.

3.19. How could the reference portfolio be adjusted for credit risk?\(^\text{11}\)

For debt instruments, the effect of credit risk would need to be eliminated from the total bond yield. The effect of credit risk usually comprises two components: the expected credit losses and the unexpected credit losses (i.e., compensation for bearing that risk). There is a wide range of practices used to estimate the required deduction for credit risk inherent in bond yields. Observed practices include:

i. **Market-based techniques**: Credit Default Swap (CDS) spread, where available, is used as a measure of the inherent credit risk in bonds and comprise the expected as well as the unexpected credit losses. An advantage of this approach is that the inherent bond credit risk is directly and instantly reflected in the CDS spread. A disadvantage is that it may capture additional risks (e.g., counterparty credit risk) and costs and, as such, may overestimate the bond credit risk. On the other side the CDS premium reflects the possibility that the CDS provider may default – and therefore the CDS premium is lower than it would be were this not the case – and therefore the CDS could underestimate the bond credit risk (where this is the case it can result in the illiquidity premium being overestimated).

ii. **Structural-model techniques** such as the Merton Model, Leland and Toft Model and EDF-Based Model. These models put in relation the capital structure of a company to an option on the equity of the same company and the value of its debt. For further information see the IAA Discount Rate Monograph Section IV and Agrawal, Arora and Bohn.

iii. **Expected / Unexpected Credit Loss (ECL / UCL) models**: ECL models usually comprise an estimation of the probability of defaults (including the future cost of downgrades) and an estimation of the loss given default. One could leverage on models developed for calculating the IFRS 9 lifetime impairment provision (e.g., panel logit models, dynamic transition matrix models). Usually based on historical information, point-in-time adjustments might be needed to calibrate estimations to current economic situation and forward-looking information (e.g., factor ratio models, scorecard models). UCL models are based on an adjustment to reach a selected

\(^{11}\) Consistency with what the entity is doing under IFRS 9 (impairment provisions), might be discussed later.
percentile credit loss level (confidence level approach). UCL could also be estimated as the compensation required by an investor to bear the credit risk associated with the instrument (cost of capital approach).

NB - several of the above approaches used to estimate the deduction for credit risk are complex and as such it has been observed that insurers have typically simplified expressions for the deductions required for credit risk and calibrating these expressions based on the above approaches. Examples of such expressions include:

a. Deduction for credit risk = Expected Default Rate + X% (Total Bond Spread – Expected Default Rate)

b. Deduction for credit risk = X% (Total Bond Spread)

c. Deduction for credit risk = Expected Default Rate * (1 + compensation risk)

The advantage of the first two approximations is that the credit risk premium changes as a function of the corporate spread.

3.20. How could the reference portfolio be adjusted for market and other risks?

As mentioned in paragraph B85, IFRS 17 does not specify restrictions on the reference portfolio of assets used in applying paragraph B81. For example, equity or real estate investments may also be considered in the reference portfolio. However, the estimation process may be much more challenging since many risks are specific to these investments and not necessarily related to the insurance contract characteristics. Such risks include, but are not limited to, market risk, variability in amount and timing of dividend, the risk of delay in finding a new tenant, obsolescence and unexpected deterioration.

Other market factors, such as market sentiment and market inefficiencies, influence the reference portfolio assets and might result in some fluctuations in the overall spread. Unless measured and treated separately, these factors might be attributed to the illiquidity component of the asset yield and hence would also be included in the liability discount rate.

3.21. How should the yield curve duration be extended beyond available market data?

In constructing the discount curve, a core principle is that the discount rates are consistent with observable market prices. If liability cash flows extend beyond a certain point, such discount rates may not be directly observable in the market, or market data for certain durations could be scarce. An entity may then choose to estimate appropriate rates beyond those observable in the market by interpolating between data points that are observed directly in the market, and between observable data points and rates estimated beyond the observable term structure. There are many potential interpolation approaches that can be used to derive a yield curve using interpolation and extrapolation techniques. In Chapter V of the Discount Rate Monograph some examples of possible approaches of interpolation and extrapolation are presented.
In applying an estimation technique, as per B78, an entity shall maximise the use of observable inputs and reflect current market conditions from the perspective of a market participant.

3.22. When does the observable market end?

The determination of the end of the observable market is a function of the financial market being considered and as such is potentially affected by whether the top-down or bottom-up approach is elected.

- For example, if the top-down approach is adopted and the reference portfolio comprised of debt instruments then the end of the observable market in the context of those debt instruments might need to be considered.

- Alternatively, if the bottom-up approach is adopted and the risk-free curve is based on government bonds then the end of the observable market in the context of those government bonds may be considered. If the risk-free curve is based on swap rates then the end of the observable market in the context of swap rates in that currency may be considered.

In general, IFRS 17 requires the use of market data when available. For example, if the market for the available financial instruments in the reference portfolio would end after 10 years and market data is available for a bottom-up approach up to 30 years, the entity might need to consider the suitability of using a top-down approach.

Once the financial market of interest has been determined, the longest duration is determined at which the market data is both available and relevant. Market data for longer durations can be used if market prices are available. The following criteria might be looked at to perform this assessment:

- availability of financial instruments;
- bid-offer spread;
- trade frequency; and
- trade volume.

For example, in a given market, 1, 3, 5, 7, 10, 20 and 30-year instruments may be available and 50-year instruments may infrequently be traded. In this example, since the 50-year instrument is infrequently traded, the market might not be considered active; data at the 50-year point is unlikely to be considered available and relevant for construction of the curve. The core premise in determining the end of the observable market is determining the
last point at which “available and relevant” market data exist for construction of the yield curve, consistent with paragraph B78.\(^\text{12}\)

In the bottom-up approach, it may be difficult to split the spread on the reference portfolio that is used to derive the illiquidity premium between a credit spread and an illiquidity premium. This may be especially challenging for longer durations. In those situations, estimation techniques might be used for this split. In the top-down approach, the current credit spread, excluding an illiquidity premium, is needed to determine the discount rate. Also, here the split between credit spread and illiquidity premium has to be determined and for longer durations a separate credit spread is not available and estimation techniques might be used.

3.23. Which assumptions can be made for long durations where there is not enough market observable data?

The following two approaches are often used:

- extrapolation based on last observable constant rate; and
- extrapolation of the last observable rate to an ultimate rate.

NB – there may be other approaches that are not considered here.

Extrapolation techniques based on the last observable constant rate have the advantage of simplicity and are based on the last observable information. On the other hand, using an ultimate rate might have the advantage of including additional market participant inputs (such as economic expectations) and may be considered more consistent with paragraph B82(c) (i.e., more weight on long-term estimates than on short term fluctuations). Setting an ultimate level is discussed in question 3.24.

The rates to be used and derived can either be expressed as forward rates or as spot rates. The use of one form or the other requires some expert judgement and can be translated back in the other form. Forward rates are frequently used to represent future implicit market rate expectations. Spot rates are generally used to derive today’s market price of a future cash flow. The final assumed curve may be expressed in both forms to ensure it is balanced with market reasonable expectations (e.g., it may be desirable to avoid important jumps and / or cliffs). One of the criteria commonly adopted by finance practitioners and academics for judging yield curve construction is that forward rates are continuous. Reasons for this include that discontinuity in forward rates implies either implausible expectations about future short-term interest rates, or implausible expectations about holding period returns (McCulloch and Kochin [2000], J. Huston McCulloch and Levis A. Kochin.

\(^{12}\) In other frameworks, such as Solvency II, a similar concept is referred to as the “last liquid point” however IFRS 17 guidance does not contain this phrase.
In any extrapolation model, the level and position of the end points are required. As such, the year at which the ultimate rate is achieved needs to be set, and would depend on considerations related to how the ultimate rate was derived. It is interesting to note that if the same assumption is used, an ultimate spot rate would require a much longer convergence period than an ultimate forward rate in order to produce equivalent results.

3.24. How is the ultimate rate level set?

In the process of setting the ultimate rate, both retrospective and prospective approaches might be considered. According to paragraph B44 “Estimates of market variables shall be consistent with observable market prices at the measurement date. An entity shall maximise the use of observable inputs and shall not substitute its own estimates for observable market data”. Further, the information used in the estimation would need to be appropriate for the expectations for the long durations of the ultimate rate.

A retrospective approach has the advantage of simplicity. However, macroeconomic fundamentals may have changed over time. Furthermore, the choice of the starting point could be considered to be arbitrary. The observed period may be chosen to be long enough to eliminate or significantly reduce cyclic effects. Examples of retrospective approaches include using an arithmetic mean (with assumed underlying normal distribution) or a geometric mean (with assumed underlying lognormal distribution) of the historical nominal interest rate or real-rate.

A very simple prospective approach would be to use the forward rate or spot rate at the last liquid point. Another approach might be to make use of well-known economic metrics reflecting market participant expectations. Examples are the central bank inflation target or neutral rates\textsuperscript{13} and OECD GDP growth forecasts.

One might also want to use historical observations and adjust them to obtain a realistic rate in a prospective approach. Economists have studied the decrease of the real interest rates around the world over the past decades e.g., (Rachel, 2015). Depending to which extent the economy of a country or currency is open, global developments influence the local interest rates. Some argue that there is a global long term real risk-free rate and that differences in the nominal rates are only caused by differences in the targeted inflation rate of the central banks. Others point to differences in the long-term rates between currencies that are difficult to explain. The decline in the real rate is a global trend however. Understanding this trend may help in setting prospective assumptions. Rachel (2015) identifies possible causes of the decline in the long-term rate. Some of them may revert and cause the real rate to increase, while others are unlikely to revert.

\textsuperscript{13} The neutral (or natural) rate of interest is the rate at which real GDP is growing at its trend rate, and inflation is stable. It is attributed to Swedish economist Knut Wicksell, and forms an important part of the Austrian theory of the business cycle.
Due to increasing globalisation, real rates across groups of countries with similar economic environments have the tendency to be closer together. See also question 3.4. As such, for these countries the same ultimate real rate may be used for liabilities with similar liquidity characteristics. The nominal rates have to be corrected for inflation. This might be the inflation targeted by the central bank.

**Cash flows that vary based on the returns of any financial underlying items**

3.25. Why is it important to distinguish between the nature of the dependency between cash flows and underlying items?

Cash flows may depend on the return of financial underlying items\(^{14}\). It is important to distinguish between a linear and a non-linear dependence. A non-linear dependence can be, for example, caused by a combination of dependence of the cash flows on the return of financial underlying items and a guarantee on the return of those financial underlying items. The valuation approach to be used in the situation of a linear dependence is discussed in question 3.26 and the valuation approach to be used in the situation of a non-linear dependence is discussed in question 3.27.

3.26. How are cash flows, that do vary based on the returns of any financial underlying items, discounted?

Paragraph B74 (b) provides guidance for cash flows that vary based on the returns on any financial underlying items. These cash flows shall be:

(i) discounted using rates that reflect that variability; or

(ii) adjusted for the effect of that variability and discounted at a rate that reflects the adjustment made.

This means that projection assumptions should be consistent with discounting to ensure an appropriate approach whether deterministic or stochastic methods are used. Deterministic methods are possible where there is linear dependence, i.e., where the insurance contract has no embedded options or guarantees.

Under (i), cash flows are projected based on the expected risky returns of the financial underlying items. If the dependence is linear, this might be done using a deterministic real-world projection rate (or curve), i.e., including a risk premium. In that case, the discount rate (or curve) to be used shall reflect that variability, and thus, also include a risk premium.

Under (ii), cash flows are adjusted for the effect of that variability. Again, if the dependence is linear, one might project cash flows using investment returns implied by a deterministic

\(^{14}\) As stated before, one must be careful in distinguishing cash flows that do and do not vary based on the returns on any financial underlying items.
risk-free rate (or curve). In that case, the discount rate (or curve) to be used shall also be on a risk-free basis.

Both approaches avoid any valuation mismatch and double counting, since the discount rate is consistent with the rate used for the cash flow projection. Theoretically, both valuation approaches are expected to lead to the same result.

3.27. What approaches can be used if the dependence of the cash flows on the financial underlying items is non-linear?

As discussed in paragraph B76, cash flows could vary with returns on financial underlying items, but be subject to a guarantee of a minimum return. These cash flows do not vary solely based on the returns on the financial underlying items, because there might be some scenarios where the cash flow will not vary based on the financial underlying items, e.g., when the guarantees are in-the-money. This is an example of a non-linear dependence.

Here are some approaches (but not an exhaustive list) that might be used in the valuation if the dependence of the cash flows on the financial underlying items is non-linear (paragraph B77), noting the requirement for the measurement to be consistent with observable market prices (paragraph B48):

- Stochastic modelling techniques based on risk neutral scenarios for investment returns on underlying items. In this technique, the projected average investment returns on the financial underlying items are calibrated to be equal to the deterministic risk-free discount rate (with adjustment for liquidity as appropriate). In each scenario, the net present value is calculated. The value of the cash flows of the insurance contract is equal to the average of the net present values of all scenarios.

- Stochastic modelling techniques based on real world scenarios for investment returns on underlying items. The financial underlying items are projected on a stochastic real-world basis. The discounting is done with a stochastic real-world deflator set, which is a set of interest rates that ensures the same valuation outcome as using risk neutral scenarios. (See IAA Monograph on Stochastic Modeling.) Also, in this approach, the net present value is calculated for each scenario. The value of the cash flows of the insurance contract is equal to the average of the net present values of all scenarios.

- Replicating portfolio techniques (paragraphs B46 and B47). These are discussed in question 3.29.

- A closed form solution might also be used where this exists depending on the nature of non-linear dependence.

---

3.28. When do cash flows need to be disaggregated?

Paragraph B77 states that an entity is not required to divide estimated cash flows into those that vary based on the returns on financial underlying items and those that do not. If it does not, it shall apply discount rates appropriate for the estimated cash flows as a whole; for example, using stochastic techniques.

In some cases, it might be easier to disaggregate cash flows than to apply discount rates appropriate for the estimated cash flows as a whole. One example might be a life insurance contract that provides a fixed death benefit plus the amount of an account balance if the insured person dies, and the account balance if the contract is cancelled. In this case, dividing the cash flows and applying different approaches might be practical for cash flows that vary based on the returns on financial underlying items vs those that do not.

In some other cases, it might be easier using stochastic techniques than trying to divide the cash flows. This could be the case when cash flows do vary with returns on financial underlying items but are subject to a guarantee of a minimum return.

3.29. How can replicating portfolios be used?

Paragraph B46 states that “an important application of market variables is the notion of a replicating asset or a replicating portfolio of assets. A replicating asset is one whose cash flows exactly match, in all scenarios, the contractual cash flows of a group of insurance contracts in amount, timing and uncertainty. […] If a replicating portfolio exists for some of the cash flows that arise from a group of insurance contracts, the entity can use the fair value of those assets to measure the relevant fulfilment cash flows instead of explicitly estimating the cash flows and discount rate.”

It might not be possible to find a replicating asset that exactly matches the insurance contract cash flows in all scenarios. Nonetheless, replicating assets may exist for some of the cash flows that arise from insurance contracts. One may also strive to find a portfolio of assets that will reproduce characteristics of some insurance contracts. As per paragraph B48, judgement is required to determine the technique that best meets the objective of consistency with observable market variables in specific circumstances. The general process might start with the simplest method and progresses to the use of more involved methods as necessary.

For example, such techniques might include the following assessments of insurance contract cash flows while maintaining non-financial risk assumptions at expected values:

i. Asset cash flow matching: Insurance contract cash flows are replicated in terms of amount and timing with available asset cash flows. This method is similar to building a reference portfolio.

ii. Optimisation: Assets are then chosen to match, as closely as possible, the key financial risk metrics related to these cash flows (e.g., duration matching).
iii. Dynamic replication: Stochastic valuation techniques are used to derive risk-factor sensitivities for the insurance contract cash flows that can be replicated directly.

The choice of method depends primarily upon the nature and complexity of the asset or liability under consideration and the purpose of the replicating strategy. For example, if the asset or liability is relatively simple, it might be possible to identify a pure replicating portfolio (e.g., capital guaranteed equity product and a vanilla European equity option). However, for more complex assets or liabilities, such corresponding assets may not exist, even theoretically. In this case, optimization techniques might be used to match the financial risk metrics as close as possible (e.g., path-dependent guarantees proxied using a portfolio of vanilla and exotic options). In other complex cases, optimization techniques may deliver poor results, hence the need to make use of dynamic replication techniques.

3.30. How is the discount rate adjusted for illiquidity if cash flows do vary based on the return of financial underlying items?

The response to questions 3.14 to 3.17 explain the assessment of contract liquidity and the resulting application of liquidity premiums in discount rates.

Consistent with paragraph B74 (b), if the cash flows that vary based on the return of financial underlying items are based on a projection of returns that include an illiquidity premium, this illiquidity is logically also reflected in the discount rate. If the cash flows that vary with the return on financial underlying items are projected without an illiquidity premium, the discount rate is chosen accordingly.

Cash flows that accrue to the holder of an insurance contract may depend on a combination of the return on financial underlying items, a guarantee on the return of the financial underlying items and other insurance cash flows subject to non-financial risk. All the following elements contribute, depending on their significance in the value of the cash flows, to the overall illiquidity:

- the illiquidity premium from the financial asset underlying the contract that is passed to the policyholder in so far it is included in the projection;
- the guarantee on the return of the financial underlying items; and
- other insurance cash flows subject to non-financial risk.

The requirement for consistency with observable market prices (paragraph B48) implies that any liquidity premium adjustments made in the valuation of options and guarantees would need to be followed by a consideration of the calibration of stochastic models to ensure that market consistency is maintained.

As discussed in question 3.15, the risk adjustment reflects the uncertainty of non-financial risk and is distinct from the other fulfilment cash flows which can be discounted using a discount rate that is appropriately adjusted to reflect liquidity characteristics.
3.31. How is the present value of future cash flows adjusted for financial risk?

In a market consistent projection, either using risk neutral or real world techniques with deflators, market variables associated with future cash flows are calibrated to be consistent with observable market prices (as required by paragraph B44). This ensures that the cash flows are implicitly adjusted for financial risk in a matter consistent with the pricing of financial instruments. This implicit adjustment for financial risk is released over the duration of the contract and accounted for as financial risk.

**Premium Allocation Approach (PAA)**

3.32. Under which circumstances is discounting required for a group of contracts subject to the PAA in measuring the liability for remaining coverage?

If the entity uses the PAA for a group of insurance contracts, as per paragraphs 53-59, discounting is only required in special circumstances in the liability for remaining coverage:

- For a group of contracts with a significant financing component where the PAA is applied, unless, at initial recognition, the entity expects that the time between providing each part of the coverage and the related premium due date is no more than a year (paragraph 56); and

- For contracts that have become onerous (paragraph 57), unless time value of money for the liability for incurred claims is not considered under paragraph 59.

3.33. When required, which discount rates are used for the liability for remaining coverage for contracts that have a significant financing component within a group of contracts where the PAA is applied?

For the liability for remaining coverage of contracts with a significant financing component within a group of contracts where the PAA is applied, as per paragraph 56, the cash flows might be discounted. The discount rate is always the locked-in rate at inception of the contract (paragraph B72(d)).

3.34. When required, which discount rates are used for onerous contracts where the PAA is applied?

If the group of insurance contracts becomes onerous (as per paragraph 57 (b)), the difference between the carrying amount of the liability using PAA (paragraph 55) and the fulfilment cash flows that relate to remaining coverage of the group GMA (applying paragraphs 33-37 and paragraphs 86e-92) should be calculated. The calculation of liability values under the GMA is conducted at either the current rate or the locked-in rate at inception of the contracts for the P&L if the OCI option is used (questions 3.36 - 3.41).

3.35. When required, which discount rates are used for the liability for incurred claims?

For incurred claims, discount rates are used unless cash flows are expected to be paid or received in one year or less from the date the claims are incurred the GMA is used without
a CSM, which is not applicable for the liability for incurred claims. The calculation of liability values under the GMA is conducted at the current rate for the balance sheet or at the locked-in rate for the P&L if the OCI option is used. If the PAA is used, the locked-in rate at the date of the incurred claim is used. If the GMA is used, the locked in rate is determined at the date of the inception of the contract.

Locked-in rates

3.36. What interest rate is accreted on the CSM?

For contracts without direct participation features, the interest rate accreted on the CSM is based on the discount rates determined at initial policy recognition for cash flows that do not vary based on the return of financial underlying items (paragraph B72(b)). It may include an illiquidity premium. This is referred to as the locked-in curve.

IFRS 17 is not specific regarding the method to roll forward the curve. One approach might be to derive each year’s discount factors with the forward rate for that year, from the locked-in curve. This forward rate would be the rate to accrete on the CSM.

If there are direct participating features, the entity’s share of the profit is discounted using current rates (paragraphs B74b).

3.37. What interest rate is used to measure the changes in the CSM?

For contracts without direct participating features in the contract, the interest rate used to measure the changes in CSM is the same as the interest rate described in question 3.36. It is the interest rate accreted on the CSM is based on the discount rates determined at initial policy recognition for cash flows that do not vary based on the return of financial underlying items.

If the VFA is used, changes are measured using the current rate.

3.38. What is the locked-in yield curve when the OCI option is used for groups of insurance contracts for which changes in assumptions that relate to financial risk do not have a substantial effect on the amounts paid to policyholders?

For groups of insurance contracts for which changes in assumptions that relate to financial risk do not have a substantial effect on the amounts paid to policyholders, and the OCI option is used, the change in the present value of the cash flows presented in the P&L is based on the locked-in curve. That means that the discount rates are determined on the yield curve at the date of initial recognition of the group of contracts or the date of the claims (paragraphs B72 (e)(iii)), applying paragraph 36 to cash flows that do not vary based on the returns on any financial underlying items.
3.39. What is the locked-in rate for groups of insurance contracts for which changes in assumptions that relate to financial risk have a substantial effect on the amounts paid to policyholders?

These contracts typically have participating features, but fail to meet the definition of “Direct Participating” contracts. If the entity plans to recognise insurance finance income or expenses in OCI, discount rates are used that allocate the remaining revised expected finance income or expenses over the remaining duration of the group of contracts at a constant rate\(^\text{16}\). (Paragraphs 88(b) and B132).

3.40. Can a single equivalent discount rate be used instead of the locked-in discount curve?

See question 3.10 for introductory context.

The locked-in curve is determined at initial recognition and if it were to be translated into a locked-in constant rate the pattern of cash flows at initial recognition would presumably be used in the derivation. Potential challenges that may occur in the subsequent use of this locked in rate are as follows:

- One purpose of the locked-in discount curve is to measure the changes to the CSM for insurance contracts without direct participation features. A change to the CSM would only arise if the pattern / level of cash flows was altered. Since the locked-in constant rate at inception would be derived based on the pattern of cash flows at inception application of this rate to an altered pattern of cash flows may be inappropriate. To gauge the materiality a comparison of the originally derived locked-in rate and the revised locked in constant rate based on the new pattern of cash flows would be required.

- Another purpose of the locked-in discount curve is to accrete interest on the CSM. Given this different purpose, the use of the locked in constant rate based on the pattern of liability cash flows may be inappropriate for interest accretion. Rather a locked-in discount rate based on equating the expected CSM interest accretion may be more relevant. Further challenges similar to the above may be encountered when the pattern / level of liability cash flows changes, changing the CSM and potentially the equivalent locked-in discount rate.

3.41. How is the average locked-in curve determined for a group of contracts?

The discount rate for the calculation of the CSM at issue for contracts in a group could be determined in, amongst others, any of the following ways.

\(^{16}\) See also example 15 of the Illustrative Examples
a. Calculating the CSM at issue for each contract within the group using the discount curve at each contract’s respective issue date – i.e., a single curve would not be used. This, however, might be an impractical implementation option.

b. Calculating the CSM at issue for the group of contracts as at the date of initial recognition using the discount curve as at the date of initial recognition. This is thought to be consistent with IFRS17 because the Standard refers to the date of initial recognition for the group and not the date of initial recognition of individual contracts. See paragraph 25 for the definition of the date of initial recognition of a group.

c. Calculating the CSM at issue for the group as at the date of initial recognition using a weighted average discount curve (paragraph B73). To apply this approach suitable weights would need to be defined as they are not specified in the guidance. One potential option for weighting might be to use the measure of coverage units. Note that as per paragraph 22 the dates of initial recognition should not include more than one year.

The methodology for calculating the locked-in curve across one or more reporting periods would be driven by the option chosen above. As per paragraph B73 a weighted average discount curve might be created with a potential option that might exist for weighting being the measure of coverage units.

- If options a. or c. above were chosen then the locked-in curve would be a weighted average curve of the specific curves used (i.e., the curves to be weighted would be from the actual issue dates).

- If option b above was chosen then the locked-in curve would be a weighted average curve of the curves at the date of initial recognition. That is, there would only be a single curve based on a single day from each reporting period which would then be weighted using the selected measure.

When calculating weighted average discount curves, one approach might be to average discount factors.

Chapter 4 – Risk Adjustments for Non-Financial Risks

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality

4.A. What does this chapter address?

This Chapter considers the criteria and measurement of the risk adjustment for non-financial risk required as part of the General Measurement Approach under IFRS 17 including the purpose and general requirements of the risk adjustment, what risks would typically be covered and specific considerations in determining the risk adjustment. This note discusses how to reflect risk mitigation such as diversification and risk sharing, catastrophic and other infrequent events, qualitative risks considerations, use of different approaches by line of business, and general considerations in selecting and calibrating a risk adjustment approach. For detailed risk adjustment methods and how to apply them, reference is made to the IAA Monograph on Risk Adjustments. This Chapter also covers high level disclosure requirements including confidence level disclosure, and issues around allocation of risk adjustments to a lower level.

In this Chapter, the term “risk adjustment” refers to the “risk adjustment for non-financial risk”, as defined in IFRS 17. In other contexts, risk adjustments may be referred to as risk margins

4.B. Which sections of IFRS 17 address this topic?

Paragraphs 37, 81, 101, 117-119 and B86-B92 provide guidance on this topic.

BC 206 - 217 also provides background on the subject.

4.C. What other IAA documents are relevant to this topic?

To support the selection of an approach or approaches for estimating the risk adjustment, an educational IAA Monograph: Risk Adjustments under IFRS 17 has been produced. The main intention of the Monograph is to provide focus on methodologies and approaches, to document and build on common approaches that have been developed so far, and to explore ways in which IFRS 17’s entity-specific approach may be incorporated into them
4.1. What is a risk adjustment?

Under IFRS 17, insurance contract liabilities are principally measured as defined in paragraph 32:

‘On initial recognition, an entity shall measure a group of insurance contracts at the total of:

(a) the fulfilment cash flows, which comprise:

(i) estimates of future cash flows (paragraph 33–35);

(ii) an adjustment to reflect the time value of money and the financial risks related to the future cash flows, to the extent that the financial risks are not included in the estimates of the future cash flows (paragraph 36); and

(iii) a risk adjustment for non-financial risk (paragraph 37).

(b) the contractual service margin, measured applying paragraph 38–39.”

The “risk adjustment for non-financial risk” is a defined term in IFRS 17.

Appendix A states - “the compensation an entity requires for bearing the uncertainty about the amount and timing of the cash flows that arises from non-financial risk as the entity fulfils insurance contracts”. A similar definition is also included in paragraph 37.

This Chapter primarily discusses the risk adjustment for non-financial risk of insurance contracts accepted by the entity. The risk adjustment for ceded reinsurance (referred to as reinsurance held in IFRS 17) is governed by paragraph 64. The application of risk adjustments for ceded reinsurance is discussed in Chapter 9 – Reinsurance of this IAN.

4.2. What is the purpose of the risk adjustment in IFRS 17?

Paragraph B87 states:

The risk adjustment for non-financial risk for insurance contracts measures the compensation that the entity would require to make the entity indifferent between:

(a) fulfilling a liability that has a range of possible outcomes arising from non-financial risk; and

(b) fulfilling a liability that will generate fixed cash flows with the same expected present value as the insurance contracts.

As such, it measures the value of a liability, related to unexpected costs, that the entity places on the uncertainty and variability (see Question 6.6) inherent in insurance cash flows. As IFRS 17 provides only the principles regarding how this should be done, it will be important to those who determine and rely on such values that the quantification of such a liability value be based on methodologies and / or approaches that are robust and are a fair reflection of this value.

As most users only see what is published in the entity’s financial statements, it is important that these liability values, and changes in such values, are based on an adequate understanding of the basis on which the risk adjustment is determined and of any changes
in that basis. This understanding will underlie the entity's ability to provide appropriate disclosures as required by IFRS 17. The entity's understanding will enhance its communications, enable consistency to be recognised and allow relevant comparisons to be made, as appropriate.

An important aspect of the communications among those responsible for determining an entity's risk adjustment is the explanation and insight regarding how the entity's views with respect to the compensation it requires for bearing risk and uncertainty has been incorporated in the determination of the risk adjustment. Such communications will be expected to reflect a thorough understanding of the entity's views with regards to risk aversion, risk diversification and the uncertainty surrounding the values being estimated.

4.3. What are the IFRS 17 requirements for risk adjustment?

IFRS 17 does not provide guidance on appropriate techniques and methods to set the risk adjustment. In paragraph 37, it simply requires that:

“An entity shall adjust the estimate of the present value of the future cash flows to reflect the compensation that the entity requires for bearing the uncertainty about the amount and timing of the cash flows that arises from non-financial risk.”

The application guidance states, in paragraph B91, that a risk adjustment should possess the following five characteristics:

(a) “risks with low frequency and high severity will result in higher risk adjustments for non-financial risk than risks with high frequency and low severity;

(b) for similar risks, contracts with a longer duration will result in higher risk adjustments for non-financial risk than contracts with a shorter duration;

(c) risks with a wider probability distribution will result in higher risk adjustments for non-financial risk than risks with a narrower distribution;

(d) the less that is known about the current estimate and its trend, the higher will be the risk adjustment for non-financial risk; and

(e) to the extent that emerging experience reduces uncertainty, about the amount and timing of cash flows, risk adjustments for non-financial risk will decrease and vice versa.”

It should be noted that the risk adjustment relates only to non-financial risks inherent in the insurance contract and its cash flows. Paragraph B86 states that

“The risk adjustment for non-financial risk relates to risk arising from insurance contracts other than financial risk. Financial risk is included in the estimates of the future cash flows or the discount rate used to adjust the cash flows. The risks covered by the risk adjustment for non-financial risk are insurance risk and other non-financial risks such as lapse risk and expense risk (see paragraph B14).”

Risks reflected through the use of market consistent inputs are excluded. Other Non-financial risks that may not arise directly from the insurance contracts, such as asset-liability mismatch or general operational risks, should not be reflected in the risk adjustment
for non-financial risks (See question 4.7 for a fuller discussion of which non-financial risks are considered.).

This general guidance means that there is no single right way for an entity to set the risk adjustment. In general, there are other important considerations that will be relevant to how an entity determines its approach to estimating the risk adjustment:

- consistency with how the insurer assesses risk from a fulfilment perspective;
- practicality of implementation and ongoing re-measurement; and
- translation of risk adjustment for disclosure of an equivalent confidence level measure.

Therefore, a variety of methods are potentially available, although their ultimate usage depends on the extent to which they meet the criteria above, given the specific circumstances of the company. Potential methods include, but are not limited to, quantile techniques such as confidence level or CTE, cost of capital techniques, or even potentially simple techniques such as directly adding margins to assumptions or scenario modelling.

There are also disclosure requirements related to the risk adjustment (see question 4.15) and chapter 15.

4.4. What is the role of actuarial input on risk adjustment?

In actuarial terms the risk adjustment is intended to reflect the value of the uncertainty inherent in the insurance cash flows under the contract. It is expected that actuarial input, both quantitative and qualitative, will be needed.

This actuarial input falls into four parts and can:

- assist in understanding and assessing the risk aversion of the entity (its attitude toward risk see questions 6.9 & 6.10), as it relates to the uncertainty and variability of insurance cash flows, and in understanding the extent to which the entity considers “the degree of diversification benefit the entity includes when determining the compensation it requires for bearing that risk” [paragraph B88(b)].

- provide quantitative measures to help evaluate the variability inherent in the insurance contracts being valued and the uncertainty which underlies such quantitative measures.

- assist in designing an approach to assess a value in terms of the compensation for bearing risk that reflects the entity’s risk aversion, in the context of the relevant risks, and in the context of the diversification affecting the compensation for such risks.

- provide explanations and insights to help in communicating the understandings and judgements involved, such that the entity’s board and management can have the appropriate level of direction and oversight regarding how the risk adjustment is determined.
4.5. What is the role of judgement in estimating the risk adjustment?

Judgement may be needed for a variety of reasons including, but not limited to:

- in the selection of the approach to estimate the risk adjustment,
- in the assessment of the entity’s risk aversion,
- in the estimation and assessment of variability and uncertainty, depending on the data available,
- in the assessment of diversification, depending on the complexity of the business written, and
- in the assessment of how risk aversion interacts with variability and uncertainty in the determination of the risk adjustment.

In general, it will be important that the entity’s board and management properly understand the process and the judgements used to determine the entity’s risk adjustment and how their oversight and management roles and responsibilities are being satisfied.

4.6. What does “risk” mean in this Chapter?

The word “risk” can have a variety of meanings, in the context of insurance.

- It can mean the two-sided risk that an outcome be greater or less than the estimated expected value of that outcome, as a result of variability and uncertainty. This is the meaning intended in this Chapter. To emphasise this, this Chapter sometimes refers to “risk (variability and uncertainty)”.
- It can mean the one-sided risk that an outcome will be worse than its expected value.
- It can refer to the subject of the insurance.
- It can refer to the insured events.

In this Chapter variability refers to the statistical variation inherent in the insurance process. This is amenable to statistical analysis of experience data. Given enough data, it can be quantified in terms of the variance and higher moments of a suitable probability distribution.

The concept of uncertainty is used here to depict a concept of risk that is broader than statistical variability. Some common aspects of uncertainty can include:

- Uncertainty in the estimates of expected value, variance and higher moments of a probability distribution. This uncertainty can be quantified as part of the statistical analysis.
- Uncertainty in the choice of probability distribution. Complex insurance processes seldom conform exactly to standard probability distributions. It may only be possible to partially quantify this uncertainty by considering alternate distributions.
Uncertainty in the experience data will arise when the data contain more or fewer extreme events than normal. The selection of a suitable probability distribution may assist in quantifying this uncertainty.

Uncertainty also arises because future circumstances can vary from the past. Environmental changes, technological changes and societal changes are all reasons why distributions based on past experience may need to be interpreted cautiously as guides to the future. Appropriate adjustments from past to future experience are a matter of judgement and introduce uncertainty into both the projected expected value and its variability.

How to appropriately reflect these sources of variability and uncertainty in the risk adjustment depends on the extent of the data and on the materiality of the potential impact on the result from the viewpoint of the reporting entity. In some cases, it may be appropriate to analyse the details extensively. Alternatively, it may be appropriate to undertake more limited analysis and to reflect other aspects of uncertainty based partly or wholly on judgement. Where data are limited, it may be necessary to rely very heavily on judgement. In assessing the extent of analysis which may be appropriate, judgement is needed as to the balance between the effort involved in undertaking deeper analysis versus whether the deeper analysis will result in a change in the estimates used to reflect risk and uncertainty that is both material and statistically meaningful.

4.7. What risks should be considered?

As discussed in question 4.3, paragraph B86 requires risk to be split between financial and non-financial risk and considered separately.

Paragraph B89 states that:

“The purpose of the risk adjustment for non-financial risk is to measure the effect of uncertainty in the cash flows that arise from insurance contracts, other than uncertainty arising from financial risk. Consequently, the risk adjustment for non-financial risk shall reflect all non-financial risks associated with the insurance contracts. It shall not reflect the risks that do not arise from the insurance contracts, such as general operational risk.”

Furthermore, financial risk is defined in Appendix A as:

“The risk of a possible change in one or more of a specified interest rate, financial instrument price, commodity price, currency exchange rate, index of prices or rates, credit rating or credit index or other variable, provided in the case of a non-financial variable that the variable is not specific to a party to the contract.”

Under these definitions, the risk adjustment for non-financial risk would include the uncertainty created by the following risks to estimates of the future cash flows. NB this list may not be exhaustive.

- Claim occurrence, amount, timing and development;
- Lapse, surrender, premium persistency and other policyholder actions;
- Expense risk associated with costs of servicing the contract;
• External developments and trends, to the extent that they affect insurance cash flows.
• Claim and expense inflation risk, excluding direct inflation index linked risk, since this is considered a financial risk.

For the risk adjustment associated with reinsurance held – see Chapter 9.

The risk adjustment for non-financial risk would not include the uncertainty created by the following:
• Operational risk (i.e., risk not driven by the future cash flow items above). Examples include legislative risk, reputational risk, business interruption / the risk of cyber attack etc.;
• Asset-liability mismatch risk;
• Price or credit risk on underlying assets.

In some instances, there may be interactions between financial variables and non-financial variables that impact expected cash flows, making the distinction between financial risk and non-financial risk less clear. For instance, policyholder behaviour may be influenced by investment performance where there are linkages between investment returns and credited rates / contractual values. In this instance, the expected cash flows reflect this influence. The risk of policyholder behaviour being different than what is reflected in estimates of the expected cash flows would be considered non-financial risk. A further example is spread compression risk due to earned / credited rate differences where crediting rates are discretionary. The risk of this discretionary spread compression being different than what is reflected in the estimates of expected future cash flows would again be considered a non-financial risk.

4.8. What is risk aversion?

Risk aversion is an entity’s reluctance to accept risk (variability and uncertainty), particularly as respects unfavourable outcomes. To overcome this aversion, entities typically expect compensation for bearing risk. The greater the risk aversion, the greater the expected compensation required. While it can be taken as a general truth that the expected compensation required increases as risk aversion increases, the relationship is not necessarily linear. For instance, the marginal compensation that an entity may require to accept marginal additional risk is likely to increase the closer the marginal additional risk brings an entity towards maximum levels of risk tolerance (i.e., risk aversion generally increases as one approaches the maximum levels of risk tolerance).

4.9. How can the actuary assess and express an entity’s risk aversion?

The entity’s board is usually responsible for its risk policy, including its policy on risk aversion. In some cases, the actuary may be able to draw on an explicit risk policy, such as that adopted by the entity’s Board, which would typically be developed in consultation with the entity’s Chief Risk Officer and / or enterprise risk committee.

In other cases, discussions with the entity’s board and management may be appropriate. Topics for discussion that the actuary may find useful include:
• comparison with similar entities in the market;
• discussion of stress scenarios, both short and long term;
• the entity’s underwriting and pricing policy and practices;
• the entity’s approach to self-assessment of solvency risk with respect to capital needs and capital management; and
• the entity’s reinsurance policy and practices.

4.10. What allowance should be made for risk diversification and what level of aggregation should be used?

The risk adjustment reflects in paragraph B88(a), inter alia, “the degree of diversification benefit the entity includes when determining the compensation it requires for bearing that risk”. Note the degree and structure of risk diversification are to be included within the entity’s assessment of compensation.

Paragraph B88(a) uses the term diversification, suggesting a bottom-up approach to determining the required compensation, but does not preclude a top-down approach. If an entity uses a top-down approach, the entity can determine the total compensation that it requires for bearing non-financial risk and then allocate or apportion it. For example, the entity may allocate its risk compensation to whatever level of subdivision is required for financial reporting purposes. With this process, the extent of aggregation of the business risks for which the entity determines its total required compensation for bearing risk is the equivalent of the extent of aggregation of business over which diversification is reflected.

This aggregation encompasses all of the insurance contracts that the entity elects to include in setting its compensation for bearing risk. For example, an entity may elect to aggregate all of the insurance contracts that it writes.

A practical issue arises when evaluating the risk adjustment for the insurance written on a gross basis, i.e., without regard to reinsurance ceded. In principle, the compensation required for bearing risk would typically first consider the net risk for the entity, with due consideration given to the entity’s use of reinsurance held as a financial resource available to the entity. Consequently, the entity’s risk aversion will implicitly reflect its views as respects its net risk. To meet the requirement in IFRS 17 to estimate the risk adjustment associated with reinsurance held, it is necessary to reflect the differences in risk on a net basis versus on a gross basis, but maintain the entity’s views regarding required compensation. The objective is to “represent the amount of risk being transferred by the holder of the group of reinsurance contracts to the issuer of those contracts” as required by paragraph 64.

In some cases, the gross risk measurement might be approximately proportional to the net risk measurement and therefore the gross risk adjustment can be estimated by using a simple scaling factor applied to the net risk adjustment. In other cases, there may be quantitative and qualitative aspects of the risk and uncertainty such that the reinsurance held provides a very effective means of risk mitigation. For example, the value to the entity from the risk mitigation provided by its reinsurance held may be significantly greater than a simple scaling factor proportional to a selected risk measure. In such cases, it may be
appropriate to consider other benchmarks or risk measures that are consistent with the entity’s risk aversion (reflecting that its risk is mitigated via reinsurance) and also to consider the entity’s estimate of its costs to retain, or replace, the reinsurance held.

If a bottom-up approach to risk adjustment is adopted, the total net required compensation for variability and uncertainty is an important check on the result of this process.

The risk adjustment may reflect the impact of diversification of non-financial risk across all of the insurance contracts that the entity selects. This may be the aggregation of all contracts to take account of all possible diversification benefits, or it may be at a lower level for sub-groups comprised of specific contracts or cohorts of business. The key consideration in making this choice is how the entity considers diversification in establishing the compensation it requires.

Where the entity consists of both a parent and subsidiaries, different perspectives have been put forward on how to reflect diversification in reporting at the group versus subsidiary level. One perspective is that the risk adjustment is set to be consistent across the group—that is, the risk adjustment at the subsidiary level should be the same as, and reflect the diversification benefits assumed at the Group level. Another perspective is that the diversification benefits assumed could be different at the Group versus subsidiary level if such an approach was consistent with the approach used by the subsidiary entity management to make its entity level decisions. Which of these perspectives should apply is a policy decision for the respective entities.

4.11. What allowance should be made for large and / or infrequent and / or atypical events?

The risk adjustment is intended to fully reflect all of the uncertainty and variability in insurance cash flows, incorporating allowance for all possible outcomes in proportion to their respective probabilities. This includes infrequent and atypical events in the tail of the distribution of outcomes. Where such tail events or combinations of events are not represented in the experience data, judgement may be needed as to how great an allowance is needed. Conversely, where such events are present, judgment may be needed as to whether they are over-represented.

In suitable cases, it may be possible to fit a probability distribution that makes due allowance for extremes, based on observed experience, but the suitability of the chosen probability distribution is also a matter of judgement. It is often helpful to model extreme outcomes separately from other events.

4.12. What allowance should be made for risk sharing mechanisms?

Risk sharing mechanisms may include:

- participation;
- investment linkage;
- deductibles and excesses;
- profit sharing;
• retrospective experience rating; and
• prospective experience rating schemes, such as no-claim discounts.

No allowance is likely to be made for prospective experience rating outside the contract boundary, as this does not relate to current contracts and is better regarded as part of the underwriting process for subsequent contracts.

Risk sharing arrangements can affect the contractual insurance cash flows between the insurer and the policyholder. Such cash flows may be contingent on insurance claims or other factors which may lessen the risk and variability of the entirety of the insurance cash flows. The risk adjustment will reflect all of these contract cash flows, with due consideration to the contingencies involved.

4.13. What is the compensation that the entity requires for bearing risk?

The compensation that the entity requires for bearing risk is a matter of judgement, which is ultimately exercised by the management of the entity and governed by the Board of the entity. In many cases, this will be informed by risk management expertise but, ultimately, the judgement is a Board responsibility, based on management (and possibly actuarial) advice.

Such judgements about compensation and risk are perhaps made regularly by entities in relation to the profit margin priced into their insurance policies. Examples of how such profit margins are expressed can be observed in a variety of ways, such as:

• an overall required profit margin on business written;
• a target rate of return or margin over risk-free on total assets, capital or equity;
• different profit margins on different classes of business; depending on perceived risk;
• a target probability which may be used for solvency assessment that losses will not exceed a given percentage of net assets; and
• an analysis of the net assets and margin over risk-free return required to support the total business, on a basis such as a target probability that those assets will prove adequate and a rate of return commensurate with that risk.

It is not, however, necessarily appropriate simply to apply the profit margin basis to estimate the risk adjustment. While a profit margin would seem to be a reasonable benchmark, in many cases there are considerations that go into selecting a profit margin that would not be consistent with the IFRS 17 measurement objectives for risk adjustments. For example, operational and asset-liability matching and investment risks that are not directly related to cash flows to the policyholder might be included in the profit margin but would not be considered in the risk adjustment. In addition, the criterion for risk adjustments is expressed as an amount which would make the entity indifferent between “risky” cash flows and fixed cash flows. Profit margins frequently reflect different objectives, such as desired market share and market competitiveness, policyholder dividend considerations, and pricing sensitivities, which may not be relevant considerations for the risk adjustment.
4.14. How should qualitative risk characteristics be reflected

Paragraph B89 requires that “...the risk adjustment shall reflect all non-financial risks associated with the insurance contract ..” and paragraph B91(d) that “the less that is known about the current estimate and its trend, the higher will be the risk adjustment...”. These provisions require that allowance for qualitative risk characteristics is to be incorporated into the risk adjustment. By their nature, incorporating such factors into the assessment of the overall level of risk requires judgement.

A first step is to assign a value to the level of risk and to assess the degree of correlation with measurable risks. In simple cases, it may be appropriate to assume that the risks are independent of one another, and can be approximated by combining the standard deviations as the square root of the sum of the squares. There are concerns that the analyses of the risk involved will provide an adequate basis for more sophisticated adjustments. However, if the qualitative risks are well enough understood, it may be possible to incorporate allowance for correlation and skewness effects.

Actuaries are often confronted with situations for which information to develop assumptions for risk, including probability models, is limited. This is most frequently the case with new markets, new risks, long duration risks, and risks involving extreme or remote events, but unanticipated circumstances (“unknown unknowns”) can arise almost anywhere.

There is no single appropriate approach to reflect qualitative considerations. However, IFRS 17 provides direction for each entity to choose one or more techniques that appropriately reflect the data, the information and the results from the models available, including the risk strategy of the management, and the extent of the uncertainty. It is important that the technique used appropriately captures the potential compensation for bearing the risk (For example, a simple technique, such as adding a margin based on the estimated standard deviation may not fully allow for the risk of very low frequency but high severity outcomes. A scenario testing approach might perform better, provided suitable extreme scenarios are included. Modelling using a suitably skewed probability distribution may be another approach.).

Both simple and complex techniques may be appropriate, depending on the nature of the uncertainty, the materiality of the uncertainty, and the structure of the underlying modelling available. For example, where uncertainty is material, and is characterised by a very low frequency and high severity risk profile and probability models are available, such a risk could be captured by introducing a state or regime switch into the model.

Since, by their nature, qualitative risks cannot be measured directly, the quantification effect is based largely on judgement. Where the impact of qualitative risks could be material, and since the responsibility for the risk adjustment lies with the entity, it may be desirable for the actuary to discuss these risks with the entity.

Qualitative risks are seldom symmetrical. Because of this, it may be appropriate to make an adjustment, based on judgement, to the risk adjustment solely on the basis of knowledge of the risks involved and any observed experience that could be relevant.
4.15. What disclosures and explanations are required?

Paragraph 93 states that “The objective of the disclosure requirements is for an entity to disclose information in the notes that, together with the information provided in the statement of financial position, statement(s) of financial performance and statement of cash flows, gives a basis for users of financial statements to assess the effect that contracts within the scope of IFRS 17 have on the entity’s financial position, financial performance and cash flows. …”

The disclosures required are set out in paragraphs 93-96. Paragraphs 97-132 set out the required “explanation of recognised amounts”.

For the most part, these disclosures relate to amounts that are inclusive of risk adjustments and are discussed in other Chapters. The specific requirements in respect of risk adjustments are:

- “For insurance contracts other than those to which the premium allocation approach described in paragraph graphs 53–59 or 69–70 has been applied, an entity shall also disclose reconciliations from the opening to the closing balances separately for each of: …(b) the risk adjustment for non-financial risk; …” [Paragraph 101].

- “An entity shall disclose the significant judgements, and changes in those judgements, that were made …(c)(ii)to determine the risk adjustment for non-financial risk …” [Paragraph 117]

- “An entity shall disclose the confidence level used to determine the risk adjustment for non-financial risk. If the entity uses a technique other than the confidence level technique for determining the risk adjustment for non-financial risk, it shall disclose the technique used and the confidence level corresponding to the results of that technique.” [Paragraph 119].

Where the PAA has been applied, the applicable paragraphs requiring explanation of recognized amounts are 98 – 100 and 102 – 105. Of these, risk adjustment for non-financial risk is mentioned in each of paragraphs 100 and 104.

4.16. What explanations and disclosures might be included in the actuary’s communications?

While there is no stated requirement in IFRS 17 that the risk adjustment will be determined by an actuary, the work products and input of actuaries are very likely to be relied upon to develop, review and maintain the risk adjustment values. An important objective of the actuary’s communications is to assist the entity in developing its IFRS 17 disclosures and to enable the Board and management to better understand the way in which the actuary has undertaken his or her work. Key elements of these communications, relative to risk adjustments, may include a discussion on:

- the background to the disclosures required;
- how the compensation the entity requires for bearing risk has been quantified;
- how the entity’s risk aversion has been assessed and incorporated in considering the entity’s required compensation for bearing risk;
4.17. What are appropriate methods to allocate risk adjustments calculated at a more aggregated level to a more granular level?

IFRS 17 does not require the risk adjustment to be directly determined at any specific level of granularity; however, to obtain appropriate fulfillment cashflows for each group of contracts the risk adjustment needs to be allocated at least to the group of contracts level for various purposes (e.g., CSM, liability for onerous contracts).

If the risk adjustment is initially calculated at a more aggregated level, any reasonable method that will lead to the same total risk adjustment, were the risk adjustment directly determined at the lower level of aggregation, is appropriate to more finely allocate the risk adjustment. Such methods reflect the key drivers of the risk adjustment calculation. For example, if the risk adjustment reflects components separately determined for insurance risk, policyholder behavior risk, and expense risk, the allocation methodology would use risk drivers that appropriately attribute the impact of each of these risks to the lower levels of aggregation.

Consideration could also be given to running more complex models at a higher level of aggregation (and perhaps less frequently) and then simplified into factor matrices to use at a more granular level in the valuation.

4.18. What are appropriate ways to estimate confidence levels for disclosure when not directly available from the risk adjustment calculations?

In order to determine confidence levels, it is necessary to be able to locate the value of the Fulfillment Cash Flow of a collection of insurance contracts on the probability distribution of the present value of the cashflows for the contracts. If that probability distribution is not explicitly derived as part of the valuation process, some method or model might be needed to estimate the percentiles of that combined portfolio distribution at the amount that reflects the risk adjustment. The extent of the analysis needed for such estimation is likely to require judgement.

For large collections of insurance contracts, there may be sufficient evidence about the tail of the probability distribution.
In other cases, the form of the probability distribution might be selected based on judgement and the parameters for that probability distribution might be selected by judgement based on what is considered appropriate for the purpose of this disclosure.

NB the sensitivity of the resulting confidence level to the chosen probability distribution increases as the confidence level increases.

The relevant part of the probability distribution may be defined in terms or two of more quantiles that straddle the Fulfillment Cash Flow based on evidence and judgements which would explain the values chosen for those quantiles.

4.19. What other considerations are relevant when estimating and communicating confidence levels?

Different actuaries providing advice on confidence levels for similar reserves for similar risks may reach very different conclusions depending on the assumptions and methodology followed and on the judgement applied.

External users are likely to place significant importance on the confidence level disclosure and compare entities to their peers. As a result, this is an area where the actuary can help management understand and communicate the issues and challenges related to this important estimate and the appropriate explanation associated with this disclosure.

Estimating the confidence level disclosure will depend on how well the aggregate probability distribution is understood. When the moments of the probability distribution can be estimated, the relative uncertainty related to such estimates increases with the order of the moment estimated. Consequently, there are risks associated with interpreting the confidence level disclosure with a false sense of precision in such estimates. This risk can be mitigated by providing a better understanding around the qualitative considerations involving the level of subjectivity and judgement involved in estimating the confidence level.

In determining the confidence level using a particular technical method there are additional considerations related to how well the method reflects the full range of outcomes, and whether the method used is stable over time, is fairly representative of ongoing conditions, and can be replicated.

As the degree of uncertainty (in the confidence level estimate) increases, the need for judgement increases and, with it, the need to better understand and communicate, to the entity, both the uncertainty and the way in which judgement has been exercised.

4.20. Should confidence level disclosure be done gross or net of reinsurance?

IFRS 17 does not specify whether the disclosure of a confidence level is intended to be on a gross or net-of-reinsurance basis. The entity’s reported risk adjustment is required on a gross level as a liability. If the entity has reinsurance held, the entity also separately reports the risk adjustment associated with reinsurance held. The entity’s net risk adjustment is not reported as a separate item. However, the estimation of separate confidence levels for disclosure that correspond to the gross risk adjustment (liability) and the reinsurance held risk adjustment (asset) may present significant technical issues and may not provide the relevant information intended.
The level of disclosure is likely to be determined by market practice.

4.21. What is the appropriate granularity for disclosure of confidence levels?

Paragraph 119 requires disclosure of the confidence level associated with the risk adjustment. The standard only requires one confidence level disclosure for the reporting entity, however, it is not prohibited to provide additional disclosure at a more granular level. The overall disclosure policy of the reporting entity is relevant to determining the approach to confidence level disclosure.

4.22. To what extent is it appropriate to use analyses and measurements made for other purposes, such as pricing, embedded value, regulatory reporting or capital modelling?

IFRS 17 does not mandate particular technique(s) to determine risk adjustments, nor does it specifically limit the techniques that may be used, or provide examples of appropriate techniques.

The primary requirement in the application guidance is that “The risk adjustment for non-financial risk for insurance contracts measures the compensation that the entity would require to make the entity indifferent between:

(a) fulfilling a liability that has a range of possible outcomes arising from non-financial risk; and

(b) fulfilling a liability that will generate fixed cash flows with the same present value as the insurance contract.” (B87)

While it may often be desirable to make use of analyses conducted for other purposes, the conclusions drawn from such analyses may not be transferrable. Such conclusions depend on the perspective and purpose for which they are required. Risk adjustments are set in a fulfilment perspective in comparison to expected values (e.g., central estimates or best estimates) that are required to represent unbiased mean values. This is not necessarily true of measurements set in other contexts. The underlying rationales of market, entry and exit values and of pricing are clearly different. This means that pricing and exit value assessments of the liability may not be appropriate ways to calibrate risk adjustments.

Internal capital models that are developed within regulatory frameworks (and/or for pricing purposes) may provide a good reference for how the entity views and assesses risk. Therefore, the techniques used to measure risk and develop risk adjustments for IFRS 17 can be compared against the techniques and measurements used under such other frameworks as a means to assess for reasonableness, and to potentially leverage the underlying analyses for both purposes. However, the resulting risk adjustments would be determined based solely on the IFRS 17 criteria.

Regulatory solvency capital adequacy models that align well with how an entity views and assesses risk may, similarly, be potentially leveraged in the development of appropriate IFRS 17 techniques to measure and assess risk. However, IFRS principles for the valuation of insurance contract liabilities are not based on the solvency requirements of an insurer, so they can only be leveraged to the extent they generally reflect how the entity views and
assesses risk. Having said this, regulatory capital adequacy requirements do place constraints on the entity, and are likely to influence its views.

A further complication is that both internal and regulatory capital requirements are there to cover all of the risks faced by the entity, while the risk adjustment in the Fulfilment Cash Flows excludes risks outside the insurance contract (such as operational, asset and asset-liability mismatch risks) and risks reflected through the use of market consistent inputs (see question 6.7). Even where regulatory minimum capital is built up in an additive structure, it does not necessarily follow that the insurance components of such a structure fully represent the insurance risks, since the underlying relationships are unlikely to be fully additive.

4.23. To what extent can different approaches be used to determine the risk adjustment within the same valuation?

There is no requirement to use a single model or approach for all the business or all the risks. An entity may use a mix or blend of methods to set risk adjustments across different businesses provided such an approach makes appropriate allowance for diversification and is done in a way that can be reasonably disclosed and explained to external auditors and is relevant to users (which is likely the biggest hurdle to a mixed model approach).

Consideration could be given to running more complex models at a higher level of aggregation (and perhaps less frequently) and then simplified into factor matrixes to use at a more granular level in the valuation.

4.24. What time horizon is used in measuring the risk adjustment?

The “compensation that the entity requires for bearing the uncertainty about the amount and timing of the cash flows that arises from non-financial risk” is generally understood to mean the compensation required for bearing the non-financial risks associated with all cash flows within the contract boundary for the duration of the contract boundary.

4.25. Where the measurement of the risk adjustment utilises a separate capital measure, what time horizon is used for the capital measure?

The time horizon used for a capital measure may be different than the time horizon used in measuring the risk adjustment, without causing inconsistencies. For example, a capital measure may use a short time horizon (e.g., 1-year, with terminal provision). The measurement of Risk Adjustment may use, as input, a series of capital measures that each use a 1-year time horizon. For example, in the traditional “cost of capital” approach, the capital measure may be based on a short time horizon (using a 1-year horizon) for capital at a given point in time, then such capital measures would be projected for future time points over the contract boundary, and then each future point estimate would be multiplied by a cost of capital rate, and then discounted back to the measurement date.
Chapter 5 – Level of Aggregation

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality

5.A. What does this chapter address?

This chapter considers the level of aggregation / unit of account that needs to be considered when valuing insurance contracts within the scope of IFRS 17.

5.B. Which sections of IFRS 17 address this topic?

Paragraphs 14-24 provide guidance on this topic.

BC 115-139 also provides background on the subject.

5.C. What other IAA documents are relevant to this topic?

None
Overview

5.1. What is the purpose of aggregation?

IFRS 17 deals purely with insurance contracts and investment contracts with Discretionary Participating Features (DPF). In most instances it is likely to be impractical, however, for an entity to measure all insurance contracts at a contract unit level. Consequently, all insurance contracts in the scope of IFRS 17 are aggregated into portfolios and groups within portfolios on initial recognition and not reassessed subsequently (paragraph 24). In doing so, the IASB intends to limit the obscuring of information that would occur by offsetting onerous contracts in one group with profitable contracts in another (paragraph BC119).

5.2. What are the levels of aggregation?

In determining the level of aggregation, an entity identifies portfolios of insurance contracts. Each portfolio is divided into groups, which distinguish onerousness, and the entity aggregates individual contracts into these groupings. An entity cannot include contracts issued more than one year apart into the same group (paragraphs 16, 17 and 22). A summary of the levels of aggregation is presented in Figure 5.1 below.
5.3. At what level of aggregation are fulfilment cash flows required to be estimated?

When measuring groups of insurance contracts, an entity may estimate the expected present value of future cashflows, discount rates and the risk adjustment for non-financial risk at a higher (or lower) level of aggregation than the group or portfolio, provided the entity is able to include the appropriate fulfilment cash flows in the measurement of the group by allocating such estimates to groups of contracts (paragraph 24). This is depicted in Figure 5.2 below.
5.4. Why is the level of aggregation important?

The level of aggregation determines the recognition and measurement requirements of IFRS 17 (paragraph 24). Groups will need to be tracked and measured throughout the lifetime of the contracts.

For many entities, the grouping exercise could have significant practical and operational issues in respect of the entity's administration, valuation and accounting systems.

Identification of Portfolios

5.5. What is a portfolio of insurance contracts?

A portfolio of insurance contracts is defined in paragraph 14 as “A portfolio comprises contracts subject to similar risks and managed together”. Each portfolio forms a partition of the total insurance business of the reporting entity. Accordingly, each contract is at inception allocated to one portfolio, or may, under certain circumstances, be apportioned across multiple portfolios if the contract covers different types of risks and these risks are unbundled.

5.6. What does subject to similar risks mean?

No clear definition of similar risks is given in the Standard. Paragraph 14 states that contracts within a product line would be expected to have similar risks, and consequently could be considered as a portfolio if they are managed together.

5.7. What does managed together mean?

Again, there is no clear definition in the Standard for this term. Hence judgement is required on what constitutes managed together.

From a practical perspective, the considerations relating to subject to similar risks noted above will require a level of granularity in assignment of portfolios that, in many cases, could result in portfolios that are naturally managed together.

It is expected that the determination of the portfolio level will vary between entities, due to different sizes and complexity of entities, as well as the different ways in which business is
managed. A practical approach to determining the portfolios for an entity might rely on the internal management reporting systems.

An entity might change how it manages its business over time and, as a result, the number of portfolios might change over time. This is an anticipated response under the Standard, although it does not necessarily affect the number of groups as historical groups do not change and groups are a sub-set of the portfolios.

5.8. Can multi-peril (or multi-benefit) products be aggregated in the same portfolio?

Peril aggregation is a common feature of general insurance products. Benefit combination is also a common feature of life insurance products. If the contracts are subject to similar risks and managed together, then it could be concluded that multi-perils (or multi-benefit) contracts can be aggregated into portfolios.

Also, relevant may be the following references and TRG papers relating to the separation and combination of insurance contracts:

- Paper AP01 for the February 18, 2018 TRG meeting and discussion thereof which provide guidance on when it may be appropriate to separate components of insurance contracts.

- Paragraph 9 and paper AP01 for the May 18, 2018 TRG meeting and subsequent discussion which provide guidance on the combination of insurance contracts, and

Additionally:

- BC119 states that aggregation set by regulators serves a different purpose than aggregation for financial reporting; and

- peril type aggregation used for actuarial modelling of reserving would not necessarily be a suitable basis for aggregation given its alignment with solvency and valuation requirements.

This supports the bundling of perils within portfolios and groups from a practical standpoint, however if the contracts cover multiple perils or benefits then separation of these components may first be required. The attribution of premium income to multiple peril groupings could be challenging, particularly if those perils were not priced explicitly within an additive pricing structure. This complexity might lead to potential inaccuracies in financial reporting, notably the consideration of whether the contract groups are onerous, Materiality of the potential inaccuracies in financial reporting are a consideration for actuaries.

Although not explicitly prohibited or prescribed in IFRS 17, it is unlikely that individual multi-peril contracts would be split into separate portfolios for the purposes of measurement under IFRS 17, purely due to their multi-peril nature. This is discussed in paper AP01 for the
February 18, 2018 TRG meeting where the intention is clearly stated that a contract with legal form of a single contract would generally be considered a single contract in substance. There might be circumstances where it is not the case. The TRG observed that:

“overriding the contract unit of account presumption by separating insurance components of a single insurance contract involves significant judgement and careful consideration of all relevant facts and circumstances. It is not an accounting policy choice.” (TRG Summary Feb 18 paragraph 7(b)(ii)).

5.9. Can separate types of risk be split out from a contract?

Following deliberations at the February 2018 and May 2018 TRG meetings it is generally agreed that the lowest unit of account is the contract. There is a presumption that a contract with the legal form of a single contract would generally be considered as a single contract in substance.

However, there might be certain facts and circumstances where legal form does not reflect the substance. For example, where transactions that are typically written as separate contracts have been bundled together as one legal contract for customer convenience or where a set or series of insurance contracts with the same or a related counterparty can be treated as a single contract. This will require careful consideration of the level of interdependencies between the different components such as shared deductibles and limits and where the lapse or termination of one component results in the termination of the whole contract.

5.10. When is a contract allocated to a portfolio of insurance contracts?

Practically, at the same time as groups are defined (see question 5.13)

5.11. Are portfolios of insurance contracts fixed for all times?

Since the definition of a portfolio refers to a purely business criterion, managed together may change over time. IFRS 17 requires a current assessment for any new business written, which means that the portfolios for an entity might change over time for new business or renewal written.

5.12. Is the entity free to refine the partition of the business in force?

No. A contract is required to be assigned to a group (which is a subset of portfolio) at initial recognition of the contract.

Organisational changes in the way contracts are managed together may require further portfolios to be created for new business and / or renewed business (where this is accounted for as a new contract), but does not affect the allocation of already existing contracts which remain in their assigned groups.

Partitioning into Groups
5.13. What is a group of insurance contracts?

A group of insurance contracts is a further partition of a portfolio according to when the contract is written and expected profitability (paragraph 16 and Appendix A). Hence a "group" is a set of new business or renewal contracts, which are issued no more than 12 months apart, to be measured together. It is a sub-set of a "portfolio". Each group is sometimes referred to as a ‘unit of account’ (though this term is not used in IFRS 17).

5.14. When is an issued contract grouped?

Paragraph 25 specifies that a group of insurance contracts is recognised at the earlier of the date when insurance coverage commences or the date the initial premium becomes due or if the group of contracts is onerous, when the group becomes onerous. New contracts are added to the group as they are written, subject to them being issued no more than a year apart (see below).

An entity shall establish the group at initial recognition and shall not reassess the composition of the groups subsequently (paragraph 24), except in the cases of a specified contract modification (paragraphs 72 and 76). This applies even if contracts within a group, or the group as a whole, are subsequently found to be onerous when they were not at initial recognition.

Question 5.11 above refers to portfolios changing over time if the business manages its insurance contracts in different ways.

Significant contract modifications are covered in more detail within Chapter 14.

5.15. What is the meaning of the limitation to contracts being issued no more than one year apart at inception?

Paragraph 25 specifies the circumstances in which a group of insurance contracts is first recognised. The issue date of an insurance contract is the earlier of the beginning of the coverage period and the date the premium becomes due. An entity shall not include contracts issued more than one year apart in the same group (paragraph 22). This refers to the date of issue of the contract being recognised under IFRS 17, which is not necessarily the same as date the contract was initially written, as due to the application of contract boundary, the renewal of a long-term contract may be treated as creating a new contract under IFRS 17.

Contracts that legally bind the insurer for only a short period (e.g., most general insurance contracts) may get reissued at the renewal date. This will be a new contract under the standard and hence the renewal date forms the issue date.

A complication for general insurers is that cohorts based on accident year may not necessarily correspond with contracts issued less than one year apart.
There is no restriction against containing shorter issue periods than this and this requirement does not require that the one-year period coincides with accounting periods or calendar years.

For contracts that bind the insurer for longer periods (e.g., most life insurance contracts) it is more complex. These contracts might be guaranteed renewable and the contract legally continues subject to payment of the renewal premium due. However, although the contract legally continues, IFRS 17 may treat the renewal date as the contract boundary and the renewal as creating a new “contract” for IFRS 17 purposes separate from the exiting contract. In which case, the underlying policy contract may be treated as multiple "contracts" for IFRS 17 purposes over its life (paragraph 35). In this case "issue" date refers not to the original date of commencement but to date of the renewal that incepted the contract under IFRS 17.

5.16. How is a contract allocated to a group?

Under the GMA and VFA, each contract to be grouped is assigned to one of at least three categories:

a. Onerous (loss-making) at initial recognition;

b. no significant possibility of becoming onerous at initial recognition; or

c. any remaining contracts in the portfolio into one or more groups.

In practice, individual contract assignment might be possible, but insurers may not attempt to assess the risk exposure in full detail and will therefore choose a certain level of differentiation of contracts corresponding with such elements, such as differentiation of risk and pricing. Reasonable and supportable information is the terminology used in the standard. Paragraphs 17 and BC 129 highlight the IASB’s intention that the objective of assigning contracts to the three categories mentioned above can be achieved by assessing a set of contracts, if the entity can conclude, using reasonable and supportable information, that the contracts in the set will all be in the same group.

Under the PAA, the entity assumes contracts in the portfolio are not onerous at initial recognition unless facts and circumstances indicate otherwise (paragraph 18).

5.17. How might grouping be different for contracts with direct participation features?

When considering how to apply the grouping for contracts with direct participation features, it is important to consider how areas in respect of mutualisation between contracts and the impact of participation might affect the allocation to groups. This is the case in respect of both considering whether contracts are subject to similar risks (portfolio allocation) and the split in respect of profitability.
IFRS 17 has paragraphs specifically on mutualisation (paragraphs B68-B71 and B103). These allow that, in calculating the value of expected cash flows, an allowance can be made for cash flows originating from contracts in other groups, not just cash flows arising solely from contracts in that group. Similarly, when doing this calculation, cash flows implicitly transferred to other groups are to be excluded. Note that this ability assumes that profit from the donor group has not already been released.

Because of the allowance for cash flows to be transferred between groups, what would otherwise be an onerous group will potentially be profitable. Similarly, if a group is potentially about to become onerous, then a transfer from a profitable group is expected to prevent that.

One might even argue that there is no point in sub-dividing groups by year of issue, because cash flows from a more profitable cohort could be transferred to a less profitable cohort. The ability to transfer between cohorts means that the profitability for business written in separate periods should be less differentiated. There may bring particular operational challenges when determining the groups in respect of businesses where new policies share in profits generated by the existing book and vice versa.

However, the IASB has stipulated that groups be differentiated by not containing contracts issued more than one year apart. This is because the IASB expects that profitability would vary over time, and at the extreme one cohort might be onerous while another is profitable. The IASB did not want this information obscured by offsetting onerous contracts in one group with profitable contracts in another (see paragraph BC119 and the last two sentences of paragraph BC136).

The IASB therefore, still felt that subdivision by year of issue was appropriate, even where there were transfers of cash flows between groups (see paragraph BC138). The requirement in paragraph 22 is that an entity shall not include contracts issued more than one year apart.

Paragraph BC138 notes that the amounts to be reported for each group are specified, but it is not necessary to calculate amounts at a group level, so calculation could presumably be undertaken at a higher level and the results then allocated to each group – this is important in the context of mutualisation, as IFRS 17 assumes that the amount of any transfers will be specifically known, whereas the actual quantification is likely to vary over time as facts and circumstances change.

5.18. How might the pool of underlying items affect portfolios?

As explained in 5.5 ‘portfolios’ are defined as contracts subject to similar risks and managed together. It will be up to the entity to determine how risks and management are affected by the pool of underlying items.
For example, it might be determined that contracts are subject to different risks, and hence be in different portfolios, notwithstanding that they participate in the same pool of underlying items. Conversely, it may be that a single portfolio covers contracts that participate in multiple pools of underlying items.

5.19. How are contracts added to an existing group?

The establishment of a group can be a process that spans up to a year. The original classification of the group determines the allocation of new contracts during that period. If the expected profitability of an open group changes during that period, it might be appropriate to close the open group and open a new one if new contracts are added that differ in profitability level.

5.20. What is reasonable and supportable information when determining whether a set of contracts can be considered as a group?

Paragraph 17 indicates consideration should be given to the availability of reasonable and supportable information to justify the grouping of contracts. In the absence of such information, an entity shall determine the group to which the contracts belong by considering individual contracts.

Reasonable and supportable information could be considered to be readily available internal management and reporting information. Examples might include policy disclosure statements, valuation reports, pricing reports or other key profitability metrics presented to senior management or the Board of Directors.

Where the entity can reasonably undertake a measurement approach at an individual contract level, this would also enable a grouping assessment to be made.

5.21. What is the difference between no significant possibility of becoming onerous and other non-onerous contracts?

Paragraph BC 130 discusses the intent of this separation in a limited manner.

Internal guidance might be created by an entity that specifies the details of the metrics that are required to determine whether contracts fall into the no significant possibility group. The approach is likely to vary across entities, given the judgmental nature of this determination.

5.22. Does the liability for incurred claims need to be separated or identified by group (portfolio, underwriting year, level of onerousness)?

Paragraph 40 stipulates that:

The carrying amount of a group of insurance contracts at the end of each reporting period shall be the sum of:

(a) the liability for remaining coverage [...] and
(b) the liability for incurred claims, comprising the fulfilment cash flows related to past service allocated to the group at that date…

It is also noted that each group is a unit of account.

In practice though, it is anticipated that the outstanding claim valuation could be carried out at a different level of aggregation than the defined groups, then allocated down or aggregated up to the adopted unit of accounts. Paragraphs 24, 33 and 40 make it clear that allocating the fulfilment cash flows to groups from a higher level of aggregation, is quite acceptable for any type of valuation activity.

5.23. What happens if the interim or financial year end cut short the grouping year? Is the reported weighted discount rate restated allowing for the remaining months?

An entity may add contracts to a group, as long as they are not issued more than one year apart from any other contracts in the group. As contracts are added to a group, this may result in a change in the weighted-average discount rates at the date of initial recognition for the group. As indicated in paragraph 28, these revised discount rates are applied from the start of the reporting period in which the new contracts are added to the group. See Chapter 3, (How is the average locked-in curve determined for a group of contracts?) where various options are discussed to calculate the weighted average discount rate.

Careful consideration will be needed in respect of this paragraph when changing the weighted discount rate.

Further Disaggregation

5.24. Is it appropriate to determine groups on a more granular level than prescribed?

There are no constraints on refinement of groups beyond the minimum level prescribed (paragraph 21).

5.25. Can a group comprise of a single contract?

Yes, a group can comprise a single contract if that is the result of the grouping exercise (paragraph 23).

Regulatory Constraints

5.26. How does community rating and legislated limitations on use of underwriting variables impact grouping?

Where law or regulation specifically constrains the entity’s practical ability to set a different price or level of benefits for policyholders with different characteristics then those characteristics can be ignored for allocating policies between groups. Therefore, if a particular characteristic that is restricted would result in policies being split between onerous and other allocations, this characteristic can be ignored. The exemption cannot be applied by analogy to other items (paragraph 20).
An example would be the gender-neutral pricing regulations in Europe, where because of the legislation males and females would be included in the same group even if there is statistical evidence of differences in risk. Another example is age, gender and pre-existing conditions in health insurance which are restricted from being used for pricing by legislation and would usually result in some policies being onerous based on current prices. In these circumstances policies that would or wouldn’t be onerous due to these characteristics may be grouped together.

5.27. How should one consider regulatory pricing constraints?

The exemption in paragraph 20 applies only when law or regulation specifically constrains the entity's practical ability to set a different price or level of benefits for policyholders with different characteristics. The categorisation would therefore be applied either to the portfolio as a whole, or groupings excluding the regulatory or legal constraints. Care needs to be taken in determining the extent of the legal or regulatory constraint, and delineating it from business decisions (see e.g., paragraphs BC133-BC134).

Other Questions

5.28. How are reinsurance contracts aggregated?

The entity accounts for reinsurance contracts held separately from the underlying insurance contracts to which it relates. Entities apply the aggregation requirements in paragraph 61 to “divide portfolios of reinsurance contracts held applying paragraphs 14–24, except that the references to onerous contracts in those paragraphs shall be replaced with a reference to contracts on which there is a net gain on initial recognition. For some reinsurance contracts held, applying paragraphs 14–24 will result in a group that comprises a single contract”.

Further discussion is presented in Chapter 9 – Reinsurance.

5.29. What mismatches might arise?

The principle of IFRS 17 (paragraphs B66(b) and explained in BC298) is to separate the underlying gross liabilities from any associated reinsurance held. This means, for example, a contract which is onerous at inception on a gross basis would still be considered onerous and accounted for as such even where 100% of this risk is ceded to another party on an original terms coinsurance basis. In this example, the reinsurance held asset would not offset the impairment on the gross liability (i.e., asymmetric accounting, with the practical consequence of a day one loss from the gross liability impairment offset by income from the reinsurance ceded asset over the lifetime of the reinsurance contract).

The VFA cannot be applied to reinsurance held business, even if it is applied to the underlying insurance contracts. See chapter 9.
5.30. What are the implications of aggregation for presentation and disclosure?

An entity is required to present income or expenses from reinsurance contracts held separately from the expenses or income from underlying insurance contracts issued (paragraph 82).

Paragraph 38 requires the separate disclosure of the groups of contracts that are issued as assets and that are issued as liabilities. Groups of contracts in a liability position are those where the total insurance contract liability is positive. Groups of contracts in an asset position are those where the total insurance contract liability is negative.

Further discussion is presented in Chapter 15.

5.31. How are business combinations and portfolio transfers treated?

On acquisition of a portfolio or set of contracts paragraph B93 applies. The acquirer reassesses the groups using paragraphs 14-24 to identify the groups as if they had been issued on the acquisition date. As the contracts would all have the same acquisition date the requirement around issued less than 12 months apart would no longer be applicable. Illustrative example 14 from IFRS 17 Illustrative Examples shows the accounting for this.

A business combination will also require additional considerations in respect of the portfolios and groups to which these contracts belong. The portfolios that were split into groups based on profitability may have changed from the original entity.

When purchasing an entity, groups are assessed at the date of the business combination date (paragraph B93). However, for the original entity the assessments would remain as previously assessed and based on the original application of paragraphs 14 to 24. This will lead to different treatments between the entity and its parent group accounts with non-alignment of the aggregations.

For intra group transfers of business, if it is assessed as a transfer of business which is not an IFRS 3 business combination paragraph B93 does not apply. (This was agreed at the June 2018 IASB meeting).

Further discussion is presented in Chapter 11.

5.32. What exceptions are allowed at transition?

This will depend on which transition method is being used to measure the group of insurance contracts. Regardless of the transition method, once adopted, groups are fixed at transition and contracts remain in the same group thereafter.

If a full retrospective approach is adopted, as per paragraph C3, there are no exceptions and business written up to transition is grouped applying IFRS 17 retrospectively as if it had always applied.
If the modified retrospective approach is applied, as per paragraphs C8 and C9, the identification of groups of insurance contracts can be carried out with the information available at the transition date. Also, groups can include contracts issued more than one year apart. However, this modification can only be used to the extent that an entity does not have reasonable and supportable information to apply a retrospective approach. If the entity does have the information to make the split by portfolio/group for a particular group this information should be used.

If a fair value approach is adopted, as per paragraph C23, it is permitted (but not required) to include in a group contracts issued more than one year apart. You can only divide into groups issued within a year, or less, where you have reasonable and supportable information to make the division. The difference here is that whereas for the other two approaches you must make the divisions if you have the information to do so, for the fair value approach you are allowed (but not required) to make the divisions if you have the information to do so.

Further discussion is presented in Chapter 12.
Chapter 6 – Contractual Service Margin and Loss Component

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality

6.A. What does this chapter address?

This chapter provides information about the contractual service margin (CSM) – what it is, how it should be determined and how it might change because of a range of factors – and the treatment of the loss component of “onerous contracts”.

6.B. Which sections of IFRS 17 address this topic?

Paragraphs 38-39, 43-46 47-52 and B96-B100 provide guidance on this topic.

BC218-BC226, BC228-BC237, BC270-BC275 and BC277-BC287 also provide background on the subject.

6.C. What other IAA documents are relevant to this topic?

None
Overview

6.1. What is the purpose of the CSM?

The CSM is defined in Appendix A of IFRS 17 and represents the unearned profit the insurance entity will recognise as it provides services under the insurance contracts in a group. The CSM is a component of the insurance contract liability for a group of contracts.

It is measured at initial recognition for a group of contracts as the excess (if any) of the expected present value of cash inflows over cash outflows, within the boundary of the contract (including acquisition costs), after adjustment for non-financial risk.

If there is no excess of inflows over outflows at inception, the contract is onerous, no CSM is established and a loss component is calculated at the time of initial recognition.

Thereafter the CSM is rolled forward with interest accrual, adjustments for some experience items, cash flow estimates and risk. The loss component is allocated on a systematic basis in accordance with paragraph 50. The CSM is then released based on coverage units representing the service provided in the period and that now expected to be provided in the future.

This means that while the initial determination of the CSM for the group is a prospective calculation, thereafter it is primarily a retrospective calculation or roll forward.

The CSM reflects the IASB’s view that profit on insurance contracts should only be recognised as service is provided, consistent with IFRS 15 (see paragraphs IN7 and BC18) and not on day of policy sale.

Measurement on Initial Recognition

6.2. How is the CSM determined at initial recognition?

The CSM for a group of insurance contracts is established at initial recognition to offset any profit that may arise from just considering the fulfilment cashflows. The fulfilment cash flows include expected future cash outflows and inflows as well as the risk adjustment for non-financial risk and any pre-coverage cash flows. Therefore, at initial recognition, the CSM considers all contractual cash flows (future and past) within the contract boundary.

In the case of a profitable contract, the outcome of measuring all cash flows should be negative (total cash outflows minus total cash inflows). This asset is eliminated at contract inception by the creation of the CSM as an additional component of the liability of the group of insurance contracts. However, pre-coverage cash flows can impact the amount actually recognised on the balance sheet (see question 6.3). The outcome in the case of an unprofitable contract is discussed in question 6.4.

Other than in the case of reinsurance the CSM is subject to a minimum of zero.
There is no difference in the calculation of the CSM at inception for groups of insurance contracts without direct participation features and those with direct participation features.

The CSM at initial recognition and subsequently is determined at the level of the group of insurance contracts (i.e., the CSM does not need to be calculated at individual contract level).

6.3. What are pre-coverage cash flows?

In this chapter, pre-coverage cash flows include contractual cash flows relating to the contract that were paid / received by the insurer before the recognition date of the contract. The recognition date determines which cash flows are “pre-coverage” and which are not. Examples of pre-coverage cash flows may include:

- Premiums under the contract;
- Commissions spent due to contractual obligations with an intermediary in response to writing the contract; and
- Cost arising during the application and underwriting process (underwriting cost) and issuance cost.

Pre-coverage cash flows include any insurance acquisition cash flows for which an asset or liability is held prior to the recognition of the group that gave rise to them (see paragraphs 27 and 38). Further, this includes both cash flows that are directly or indirectly allocated to a contract e.g., acquisition cost spent without success, provided they are directly attributable at a portfolio level.

Paragraph 25 states that the recognition date of the contract is the earliest of the following:

- the beginning of the coverage period of the group of contracts;
- the date when the first payment from a policyholder in the group becomes due; and
- the date when the group becomes onerous for, a group of onerous contracts.

6.4. Can the CSM be negative at initial recognition?

Except in the case of reinsurance (see chapter 9 on reinsurance), the CSM cannot be negative and, when the calculation indicates a negative value, is instead set to zero. This results in a loss being reported equal to the amount by which the CSM otherwise would have been negative.

The negative balance is referred to as the loss component (see questions 6.26 – 6.29 on onerous contracts).
Subsequent Measurement: Contracts without Direct Participation Features

6.5. What changes are recognised in the CSM for contracts without direct participating features?

Paragraph 44 outlines how the CSM for a group of insurance contracts without direct participating features moves over time. It is calculated as follows:

\[
\text{CSM at the start of the reporting period} \\
\quad \text{plus the effect of any new contracts added to the group (see question 6.6);} \\
\quad \text{plus the value of interest accretion (see question 6.7);} \\
\quad \text{plus the changes in fulfilment cash flows relating to future service (see questions 6.8 – 6.11);} \\
\quad \text{plus the value of currency exchange differences; and} \\
\quad \text{less the amount recognised as insurance revenue because of the transfer of services (see questions 6.12 – 6.20)} \\
\]

\[= \text{CSM at end of the reporting period.}\]

6.6. What is the effect of any new contracts added to the group?

For any new contracts added to a group of insurance contracts during the reporting period, the entity includes only contracts recognised during the reporting period. New contracts can be added to the group after the end of the reporting period (subject to all contracts in the group being issued no more than one year apart), in accordance with paragraph 28.

6.7. What interest rate is accreted on the CSM?

Interest is accreted on the carrying amount of the CSM during the reporting period using the discount rate applied on initial recognition to reflect the time value of money (paragraphs 44(b) and B72(b)). This discount rate is applied to nominal cash flows that do not vary based on the returns of any underlying items. For further details on determining discount rates see Chapter 3.

6.8. Which changes in fulfilment cash flows qualify for adjusting the CSM?

Paragraph 44(c) states “the CSM is adjusted for the changes in fulfilment cash flows relating to future service as specified in paragraphs B96–B100, except to the extent that:

\begin{itemize}
  \item such increases in the fulfilment cash flows exceed the carrying amount of the contractual service margin, giving rise to a loss (see paragraph 48(a)); or
  \item such decreases in the fulfilment cash flows are allocated to the loss component of the liability for remaining coverage applying paragraph 50(b).\end{itemize}
Table 6.1 summarises which components underlying the fulfilment cash flows qualify for adjusting the CSM under the Core Requirements for without direct participation contracts.

**Table 6.1: Which changes in fulfilment cash flows qualify for adjusting the CSM?**

6.9. What is the experience investment component?

If, due to actual experience differing from expected experience, an investment component of the contract, i.e., an amount to be repaid to the policyholder under all circumstances, is not repaid in the current period, it will be repaid in future. Since this repayment was not originally included in the estimate of future cash flows, the estimate is increased by the present value of the future repayment at a later estimated repayment date.

A change in the estimate of such future cash flows adjusts the CSM (paragraph B96 (b)), i.e., decreases it by the present value of the future repayment of the investment component, applying the locked-in rate according to paragraph B72 (c).

Except for amount resulting from the discounting effect, the adjustment is reversed by a second adjustment, adding the difference between the investment component expected to be paid in the current period and the one actually paid, i.e., none, to the CSM (paragraph B96 (c)).

The opposite bookings apply if an investment component is repaid in the current period although it was expected that it would be repaid in a future period.

6.10. How are changes in the risk adjustment for non-financial risk reflected in CSM?

The CSM should be adjusted for changes in the risk adjustment for non-financial risk relating to services provided in future periods (paragraph B96(d)), subject to the condition that the CSM should not be negative. Changes in the risk adjustments for non-financial risk relating to coverage and other services provided in the current or past periods should be recognised in profit or loss.

The entity can disaggregate the change in risk adjustment for non-financial between the insurance service result and insurance finance income or expenses (paragraph 81). If the entity does not disaggregate in this way, then the entire change in risk adjustment is disclosed as part of the insurance service result.

The CSM is not affected by the approach adopted for presentation.

6.11. Does a change in the discretionary cash flows paid to policyholders during the reporting period for an insurance contract without direct participation features change the CSM?

Yes, if the entity has discretion over the cash flows to be paid to policyholders for insurance contracts without direct participation features, then a change in the discretionary cash flows is regarded as relating to future service, and adjusts the CSM (paragraph B98).

To determine how to identify a change in discretionary cash flows see paragraphs B98-B100.

Transfer of Services
6.12. How is the transfer of services determined?

The amount of CSM recognised in profit or loss for a group of insurance contracts in each period reflects the services provided under the group of insurance contracts in that period (see paragraphs 44(e), 45(e) and 66(e) and B119).

The amount of the CSM for the group at the end of the period, before allowing for the transfer of services, is after interest accretion, adjustment for changes relating to future service for cash flow estimates, premiums received and risk adjustment; investment component experience etc.

The entity allocates the CSM at the end of the period equally to each coverage unit (see question 6.13) provided in the current period and those expected to be provided in the future within the contract boundary, and recognises in profit or loss the amount allocated to the coverage units provided in the current period.

6.13. What is a coverage unit?

The coverage units establish the amount of the CSM to be recognised in profit or loss for services provided in the period. Coverage units reflect “the quantity of the benefits provided under a contract and its expected coverage duration” (paragraph B119(a)).

Aspects of IFRS 17 relevant in interpreting coverage unit are:

The coverage period is defined in IFRS 17, Appendix A as:

“The period during which the entity provides coverage for insured events. This period includes the coverage that relates to all premiums within the boundary of the insurance contract.”

The insured event is defined as:

“An uncertain future event covered by an insurance contract that creates insurance risk.”

The insurance risk is defined as:

“Risk, other than financial risk, transferred from the holder of a contract to the issuer.”

The application guidance (paragraphs B7-B32) discusses what constitutes insurance risk.

The recognition of CSM in insurance revenue as being related to the transfer of services (paragraphs 44 and 45):

“The amount recognised as insurance revenue because of the transfer of services in the period, determined by the allocation of the contractual service margin remaining at the end of the reporting period (before any allocation) over the current and remaining coverage period, applying paragraph B119.”
Paragraphs BC279-BC282 set out the IASB’s thinking and rationale for the release of the CSM and the use of coverage units for this purpose. In particular, the following were discussed and rejected by the IASB as the basis for release of the CSM:

a) pattern of expected cash flows (BC279(a));
b) the change in the risk adjustment caused by release from risk (BC279(a));
c) when the returns on investment components occur even where this drives total expected fee (BC280); and
d) release based on services other than insurance service (Last sentence of BC280).

A discussion about how to determine the quantity of benefits in an insurance contract when determining the coverage units of a group of contracts was discussed initially at the IASB’s February 2018 TRG (paper AP05) and considered further and in more depth at the IASB’s May 2018 TRG (paper AP05 and IASB TRG Meeting Summary). It was observed that:

IFRS 17 established principles, not detailed requirements, and detailed requirements would not work appropriately in all cases;

determination of coverage units is not an accounting policy choice, but requires application of careful judgement and consideration of the facts and circumstances to best achieve the principle of reflecting the services provided in each period;

the analysis of the examples discussed at the May 2018 meeting reflects the fact pattern of each example and does not necessarily apply to other fact patterns;

In considering how to achieve the principle, it was observed by the TRG members that:

a) lapse expectations are included to the extent they affect expected duration of coverage;
b) the different levels of service across periods needs to be reflected in determination of coverage units;
c) the quantity of benefits is determined from the policyholder perspective not the quantity of benefits expected to be incurred by the insurer;
d) a policyholder benefits from the insurer standing ready to meet valid claims should the insured event occur, hence the quantity of benefits relates to amounts that can potentially be claimed;
e) different probabilities of insured events across periods do not of themselves affect the stand-ready quantity of benefit provide to a policyholder, but where there are different types of insured events, their different probabilities might affect the stand-ready benefit provided by the insurer; and
f) particular method(s) are not specified by IFRS 17 and different methods may achieve the objective of reflecting the service provided in each period.

6.14. What service should be reflected in coverage units?

The IASB’s May 18 TRG considered, for contracts with direct participation features, the question of what services should be reflected in coverage units (e.g., purely insurance or insurance and investment) and the staff analysis concluded that:

IFRS 17 identifies only direct participation contracts as providing both insurance and investment services;

the reference to services in paragraphs 45 and B119 relate to insurance and investment service;

the reference to quantity of benefits in paragraph B119(a) relates to both insurance and investment services;

the reference to expected coverage duration in paragraph B119(a) relates to the duration of insurance and investment services; and

it is necessary, given the tight link of the coverage period to the provision of coverage of insured events in IFRS 17, to make a narrow amendment to clarify that, for direct participation contracts, the coverage period relates also to the provision of investment services.

Members of the TRG generally did not agree with the view that investment service was only present for direct participation contracts, and argued that insurance contracts without direct participating features can have investment components but cannot provide investment services, only insurance services. Profits are derived from investment components, but they can only be recognized in proportion to providing insurance services.

It is worth bearing in mind, that for stand-alone investment contracts with discretionary participation features, the coverage units are based on the investment service, and hence when the returns on the underlying items occur. For contracts that are measured using the VFA, coverage units can reflect investment as well as insurance services.

The way in which this is determined will need to be considered.

6.15. Are there examples available of coverage units?

The appendices of the IASB’s May 2018 TRG paper AP05 contain a large number of examples and the paper contains the IASB staff’s analysis of potential views of what coverage unit means in the context of specific facts and circumstances. These might be
helpful in aiding understanding but only in the context of the specific set of facts and circumstances outlined in the paper.

6.16. Which proxies (e.g., premium and passage of time) can be used as coverage units?

The following methods may be reasonable proxies depending on the facts and circumstances (this is a non-exhaustive list).

(i) Straight line allocation over time but reflecting the expected number of contracts in the group.

(ii) Use of maximum contract cover in each period.

(iii) Use of cover amounts for which the policyholder could validly claim each period should insured event occur.

(iv) Use of premiums, but not if they:
   a) are receivable in different periods to the insurance services; or
   b) reflect different probabilities of claim for the same insured event in different periods rather than different levels of stand-ready service; or
   c) display different levels of profitability in contracts rather than the stand-ready service.

6.17. How do you deal with multiple benefits on a single contract?

Alternative approaches which may be helpful when dealing with multiple benefits on a single contract are outlined below (this is not an exhaustive list).

- Determine coverage units based on the individual benefit components separately and adjust the CSM according to the recognition of all relevant coverage units during the period.
- Consider whether a coverage unit reflecting the characteristics of all benefits can be determined.
- Consider whether the contracts can be separated into components for the purposes of measurement. The TRG covered considerations relating to the separation of insurance components during its February 2018 meeting.

6.18. Can coverage units be calculated net of reinsurance?

No. As underlying business and reinsurance are valued and reported separately, coverage units need to be determined gross rather than net.
6.19. When does the coverage period start and end?

Appendix A defines coverage period as “the period during which the entity provides coverage for insured events. This period includes the coverage that relates to all premiums within the boundary of the insurance contract”.

Coverage would normally be the effective date of the insurance contract. In some circumstances, coverage may:

- start later, e.g., for travel insurance coverage may only start from the date of travel; or
- appear to start earlier, e.g., a reinsurance treaty may provide cover on claims notified basis (e.g., for emergence of claims not yet reported to the cedant but arising prior to the start date). However, in this case, coverage of notified claims only starts from the start date of the reinsurance contract, and would only start earlier than the start date of the treaty if the treaty also specifically covers claims notified prior to its start.

Normally coverage will cease at the end date specified in the contract, or contract boundary if earlier, or in many cases upon a valid claim arising before the end date. Depending on the nature of the contract, any claims arising from events occurring after that time may not give rise to a valid claim under the contract. Note that notification or settlement of the claim may occur after the end date and the claim amount payable ultimately may continue to develop after the end of the coverage period. However, these are part of the incurred claim liability and do not represent the provision of further coverage.

In other cases, e.g., stop loss reinsurance, while a sequence of independent events might trigger the incurrence of a claim, such events of themselves are not part of the coverage, it is the occurrence of underlying claims for amount that in total trigger a stop loss claim. Here coverage is for claim payments arising in excess of the stop loss attachment point and again coverage starts from the point at which a valid claim could be made under the contract and not the underlying individual events.

Further, subsequent events may change the amount of the claim ultimately payable but they represent development of the claim amount and not the provision of further cover, e.g., an accident may cause a disability which gives rise to the payment of an annuity for the remaining life of the person disabled. In this case, the cover is for the occurrence of an event which causes such disablement.

6.20. Can the coverage units include discounting?

Yes, coverage units can include the impact of time value of money.

IFRS 17 is silent on whether time value of money needs to be allowed for in determining the release pattern for the CSM and paragraph BC282 makes it clear that this has been deliberately left to the discretion of the reporting entity.
An example of discounting and not discounting coverage units is provided in IFRS 17 Illustrative Example 2, IE17(e).

**Subsequent Measurement: Contracts with Direct Participating Features**

6.21. How does subsequent measurement of the CSM differ for insurance contracts with direct participating features?

For insurance contracts with direct participating features, the entity substantially provides insurance and investment related services and is compensated for the services by a fee that is determined with reference to the underlying items. The CSM is subsequently measured similarly as for contracts without direct participating features (see question 6.5) except in relation to:

1. the entity’s share of the change in the fair value of the underlying items (see question 6.22);
2. the interest rate accreted to the CSM (see questions 6.23 – 6.24); and
3. any financial risk mitigation using derivatives (see question 6.25).

The amounts that adjust the CSM do not need to be identified separately. For example, entities need not identify the adjustments to the CSM for changes in the entity’s share of the change in the fair value of underlying items separately from those related to changes to the fulfilment cash flows related to future services. A combined amount can be identified for some or all of them (paragraph 45).

Please also see the answer to 8.12.

6.22. How do changes in the fair value of underlying items impact the CSM?

Changes related to the entity’s share of the fair value of the underlying items – i.e., the variable fee – relate to future service and adjust the CSM except to the extent that:

- the entity meets the conditions for the financial risk mitigation option and chooses to adopt it;
- the entity’s share of a decrease in the fair value of the underlying items exceeds the carrying amount of the CSM, giving rise to a loss; or
- the entity’s share of an increase in the fair value of the underlying items reverses losses previously recognised.
6.23. Is the CSM adjusted for changes in the effect of time value of money and financial risks not arising from the underlying items?

Changes in fulfilment cash flows arising from time value of money and financial risks are regarded as part of the variable fee and recognised in the CSM unless the changes exceed the CSM or the risk mitigation option is taken (refer paragraph B115).

6.24. Which discount rates should be used to calculate the CSM?

No explicit interest is accreted on the CSM since it is re-measured when it is adjusted for changes in financial risks.

6.25. What is required to use and the implications of using the financial risk mitigation option?

Paragraph B115 provides an option for an entity to reduce an accounting mismatch between the measurement of derivatives to mitigate financial risk and the insurance liability. Derivatives are generally measured under IFRS 9 at fair value through profit or loss. For direct participation contracts, changes in the carrying amount of the fulfilment cash flows related to financial risks adjust the CSM instead of being recognised immediately in profit or loss, regardless of whether they relate to the entity’s share of the underlying items.

An entity can choose to apply the option of not adjusting the CSM for some changes in the fair value of underlying items (paragraph 45(b)(i)) or the fulfilment cash flows relating to future service (paragraph 45(c)(i)) if it uses derivatives to mitigate the financial risk arising from the insurance contracts and paragraph B115 applies.

For without direct participation contracts, such an accounting mismatch does not arise as changes in the carrying amount of the fulfilment cash flows related to financial risks do not adjust the CSM.

Onerous Contracts

6.26. What is an onerous group of contracts and how are they treated in profit or loss?

A group of contracts is considered onerous if the CSM would otherwise be negative, i.e., there are future losses expected on the contract after including allowance for the risk adjustment for non-financial risk. This can occur at outset or occur on subsequent measurement if the following amounts exceed the CSM:

(a) unfavourable changes in the fulfilment cash flows allocated to the group arising from changes in estimates of future cash flows relating to future service; and

(b) for a group of insurance contracts with direct participation features, the entity’s share of a decrease in the fair value of the underlying items.

The amount by which the contract is onerous is recognised immediately as a loss when it is known that it is loss making (paragraph 48).
6.27. When are onerous contracts recognised?

A group of onerous contracts needs to be recognised when the group is identified as being onerous, even if this is before coverage has commenced or the first premium is due (paragraph 25).

6.28. What is a loss component?

The loss component represents the amount of losses arising from onerous contracts which are available for reversal. They are excluded from the determination of insurance revenue (paragraph 49), i.e., they are not reflected directly in the financial statements.

6.29. How is the loss component tracked over time?

The loss component is tracked and adjusted over time for further losses and loss reversals by:

allocating any changes in the fulfilment cash flows due to changes in estimates of future cash flows relating to future service, which if:

i) unfavourable increase the loss component and give rise to a further loss; or

ii) favourable reduce the loss component, give rise to loss reversal and re-establishment of CSM once loss component is extinguished.

allocating the remaining change in the fulfilment cash flow of the group on a systematic basis between the loss component and the balance of the liability for remaining coverage (paragraphs 50(a) and 51). Changes to fulfilment cash flows to be allocated (per paragraph 51) are:

i) estimates of the present value of future cash flows for claims and expenses released from the liability for remaining coverage because of incurred insurance service expenses;

ii) changes in the risk adjustment for non-financial risk recognised in the profit or loss because of release from risk; and

iii) insurance finance income or expenses.

The systematic basis used needs to ensure the loss component is extinguished by the end of the coverage period of the group (paragraph 52). This can be done for example by using:

- the same release method that would have been applied to the group if there had been CSM (e.g., coverage); or

- the opening balance of the loss component as a percentage of the future cash flows and risk adjustment relating to future service (see Illustrative Example 8).
Note that while the loss component is not specifically recognised on the financial statements a reconciliation of opening to closing balance of the loss component needs to be disclosed (see paragraph 100(b)).

6.30. How are onerous contracts dealt with if they are acquired through a transfer of business?

Paragraph B95 outlines that the amount identified as being onerous can be classified as either goodwill or as a loss on contracts acquired in a transfer. (See question 6.37 for more detail.)

Reinsurance Contracts Held

6.31. How is the CSM determined at initial recognition for reinsurance held?

A CSM is determined for a reinsurance held contract at initial recognition using the same approach as for the underlying insurance contract except the concept of an ‘onerous’ reinsurance held contract does not exist (paragraph 68). This difference means the CSM can both:

reduce the reinsurance held asset (i.e., present value of reimbursements from the reinsurance contract exceed the present value of reinsurance premiums) and therefore defer recognition of profit from the reinsurance contract; or

increase the reinsurance held asset (i.e., present value of reinsurance premiums exceeds the present value of reimbursements from the reinsurance contract) and therefore defer recognition of losses from the reinsurance contract (see paragraph 65(a)).

The following table shows the measurement of a reinsurance contract where the CSM is negative (i.e., a net cost of purchasing reinsurance - scenario 1) versus when the CSM is positive (i.e., a net gain of purchasing reinsurance - scenario 2). This assumes the risk of non-performance of reinsurer to be negligible.

Table 6.2: Illustrative example of CSM for a Reinsurance Contract

</table>
6.32. At initial recognition, does the existence of reinsurance held impact the determination of the CSM and onerous contract testing of the gross policy liabilities?

No, because the principle of IFRS 17 (paragraph B66(b)) is to separately recognise the underlying gross liabilities from any associated reinsurance held, the determination of CSM, as well as onerous contract testing of the gross policy liabilities.

As an example, a contract which is onerous at inception on a gross basis would still be considered onerous and accounted for as such even where 100% of this risk is ceded to another party on an original terms coinsurance basis. In this example, the reinsurance held asset would not offset the impairment on the gross liability (i.e., asymmetric accounting, with the practical consequence of a day one loss from the gross liability impairment offset by income from the reinsurance ceded asset over the lifetime of the reinsurance contract).

6.33. How is the CSM on reinsurance held determined at subsequent measurement?

The subsequent measurement of the CSM for reinsurance held is performed using the same approach as for the underlying insurance contract, albeit on the general measurement approach, except when the underlying gross contract(s) becomes onerous (or is already onerous and becomes more or less so) due to changes in fulfilment cash flows relating to future service. In such circumstances, the change in fulfilment cash flows for the reinsurance held also does not adjust the CSM of the reinsurance held under paragraph 66(c) ii.

Note: the criterion for not adjusting the CSM of reinsurance held does not require underlying contracts to be or have become onerous. The only requirement under paragraph 66(c) is that changes in reinsurance fulfilment cash flows results from a change in fulfilment cash flows allocated to a group of underlying insurance contracts that does not adjust the CSM for the group of underlying insurance contracts.

In these circumstances it is possible that the offsetting impact on the reinsurance held may exceed that on the underlying contracts due to accounting mis-matches that could arise between the reinsurance and the underlying contracts (e.g., due to different contract boundaries or measurement approaches).

6.34. How is the reinsurance CSM adjusted when the change in reinsurance fulfilment cash flows relates to an underlying portfolio using PAA?

When the gross liability is determined using the PAA, there are different views as to how paragraph 66(c) applies. Two of these are outlined below.

View (A): Only when the underlying portfolio is onerous is the reinsurance CSM not adjusted. The argument for this is as follows:
(i) This is consistent with the rationale given by IASB that where an underlying group becomes onerous due to changes in estimates for future service then the reinsurance CSM should not be adjusted, creating an offset (BC315);

(ii) Estimates for future service only occur under PAA when the portfolio is onerous (see paragraphs 57-58);

(iii) Criteria for not adjusting reinsurance CSM under paragraph 66(c) are that there is a change in underlying fulfilment cash flows for future service which does not adjust the CSM of the underlying group. Such change only occurs under PAA when contracts are onerous, as otherwise underlying fulfilment cash flows are not measured under PAA;

View (B): The reinsurance CSM is never adjusted when the change in reinsurance fulfilment cash flows relates to an underlying portfolio using PAA even when the underlying cash flows are not onerous as:

(i) there is no CSM under PAA, any change to reinsurance cash flows relating to underlying portfolio does not adjust the CSM of the underlying; and

(ii) the criteria in paragraph 66(c) do not require an actual change in fulfilment cash flows for the underlying, just that the change in fulfilment cash flows of the reinsurance contract that relate to the underlying and do not change the CSM of the underlying group.

6.35. How is the grouping of contracts for CSM impacted by the fact that reinsurance contracts may cover multiple years of underlying policies?

IFRS 17 prohibits grouping contracts issued more than one year apart. Reinsurance contracts held are aggregated differently to the underlying contracts (paragraph 61), in particular they are treated as a separate portfolio from the underlying and are grouped based on the characteristics and inception dates of the reinsurance contract, not the underlying.

This will require careful consideration when matching up which adjustments to the CSM are restricted (as per question 6.33) as there may be multiple underlying groups and no one to one correspondence between contracts or benefits reinsured.

Other Issues

6.36. How is the CSM calculated for business combinations and transfers of insurance contracts at initial recognition?

Unless the PAA for the liability for remaining coverage applies, on initial recognition the CSM is calculated applying paragraph 38 for acquired insurance contracts issued and paragraph 65 for acquired reinsurance contracts held using the consideration received or
paid for the contracts as a proxy for the premiums received or paid at the date of initial recognition.

If acquired insurance contracts issued are onerous, applying paragraph 47, the entity shall recognise the excess of the fulfilment cash flows over the consideration paid or received as part of goodwill or gain on a bargain purchase for contracts acquired in a business combination or as a loss in profit or loss for contracts acquired in a transfer. The entity shall establish a loss component of the liability for remaining coverage for that excess, and apply paragraphs 49–52 to allocate subsequent changes in fulfilment cash flows to that loss component.

See Chapter 11 for a further discussion of on business combinations and portfolio transfers.

6.37. How is the CSM calculated at transition?

The measurement of the CSM or loss component under the full retrospective, modified retrospective and fair value approaches at transition is discussed in Chapter 12 on Transition.

6.38. What needs to be presented?

If an entity chooses to adopt the financial risk mitigation option (see question 6.25), then it discloses the effect of that choice on the adjustment to the CSM that would otherwise have been made in the current period (paragraph 112).

See Chapter 15 for a discussion on what to present relating to the CSM.
Section B – Variations to the General Measurement Approach

This section includes three chapters that cover the variations to the GMA. These are:

- The Premium Allocation Approach – Chapter 7
- Contracts with Participation Features and Other Variable Cash Flows - Chapter 8
- Reinsurance Contracts held – Chapter 9

As discussed in Chapter 7 the PAA may be used whenever it provides a good approximation to the GMA liability for remaining coverage. It may also be used for groups of contracts with a coverage period of one year or less, regardless of whether it provides a good approximation. Many non-life insurance contracts satisfy this criterion. However, longer-term annual renewable contracts may also satisfy this criterion, if the contract boundary lies at the next renewal date.

As discussed in Chapter 8, the circumstances as to when the VFA may be used are not always straightforward especially for contracts with direct participation features which may well vary by jurisdictions. Although not insurance contracts, Investment Contracts with Discretionary Participation Features are in scope of IFRS 17 “provided they are issued by an entity that also issues insurance contracts”. If so these contracts are measured in the same was as Contracts with Direct Participation Features.

Whilst reinsurance contracts issued by an Insurer / Reinsurer are accounted for using the GMA, there are variations as to how an entity accounts for reinsurance held. This is discussed in Chapter 9.
Chapter 7 – Premium Allocation Approach

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality.

7.A. What does this chapter address?

This Chapter considers the use of the Premium Allocation Approach (“PAA”) under IFRS17 including the criteria applying to an insurance contract which must be met for an entity to choose this method, the measurement approach and the differences between this approach and the General Measurement Approach. The Chapter focuses on the “liability for remaining coverage” where most of the differences between the PAA and the General Measurement Approach are found, although minor differences for the “liability for incurred claims” are noted. Presentation and Disclosure for PAA is discussed in Chapter 15.

7.B. Which sections of IFRS 17 address this topic?

Paragraphs 18, 53-59, 69-70, 72(c), B72(d),(e)(iii), B126-B127, B133 provide guidance.

BC288–BC295 provide background on this topic.

7.C. What other IAA documents are relevant to this topic?

None
7.1. What is the Premium Allocation Approach?

The Premium Allocation Approach (PAA), which is set out in paragraphs 53-59, is a simplification of the measurement basis in IFRS 17 paragraphs 32–52 (referred to in this IAN as the General Measurement Approach (“GMA”), see the Introduction to Section A of this IAN). Paragraph 53 states that an entity may use the PAA to measure the liability for remaining coverage, if it reasonably expects that the PAA would produce a measurement for a group of contracts that would not differ materially from the one that would be produced applying the GMA, or if the coverage period of each contract in the group is one year or less. The IASB has stated there is only one model, the GMA, for measuring insurance contracts. (See question 7.2 unten).

The PAA primarily applies to the liability for remaining coverage, the obligation that relates to the unexpired portion of the coverage period. With the exception of a couple of simplifications under the PAA (paragraph 59), the liability for incurred claims is measured under the GMA, which is discussed in chapters 2 through 6.

The remainder of this chapter considers questions relevant to when and how the PAA may be used. In particular, see questions 7.10 and 7.11 for more information on how the subsequent liability for remaining coverage is measured under the PAA.

7.2. When might an entity choose to use the PAA?

Whilst the PAA represents a mathematical simplification of the GMA, when an entity decides to implement the PAA will depend on the circumstances of each entity. For example, an entity may prefer to use the PAA where it can be implemented with fewer practical changes to existing systems and processes than might be required to develop an approach to implement calculating and reporting the CSM under the GMA. However, if not all an entity’s contracts may be eligible for the PAA, then an entity may need to consider whether there are benefits to implementing the PAA for eligible contracts and developing an approach to implementing the GMA for other contracts or whether to implement the GMA for all contracts.

The PAA is similar to the unearned premium approach used by many entities for reporting unexpired coverage under IFRS 4, local GAAP and/or regulatory reporting for short duration contracts. However, the PAA is not exactly the same as some unearned premium approaches and adjustments may be required. Therefore, entities may need to consider the benefits and disadvantages of implementing the PAA or the GMA for contracts that are eligible to use the PAA.

Considerations for entities in deciding whether to use the PAA might include, for example, the extent to which existing and potential future contracts are or are not eligible for the PAA; the extent to which existing systems and processes may or may not support reporting the PAA for eligible contracts; and the additional resource and cost that may or may not be required to implement the GMA compared with PAA.
7.3. What are portfolios and groups of contracts?

An important concept to understand when reading this chapter is the level of aggregation under IFRS 17. Refer to chapters 1 Classification of Contracts and 5 Unit of Account.

7.4. When can the PAA be applied?

The PAA can be applied if the conditions in paragraph 53 are met. Paragraph 53 states:

An entity may simplify the measurement of a group of insurance contracts using the premium allocation approach set out in paragraphs 55–59 if, and only if, at the inception of the group:

a) the entity reasonably expects that such simplification would produce a measurement of the liability for remaining coverage for the group that would not differ materially from the one that would be produced applying the requirements in paragraphs 32–52; or

b) the coverage period of each contract in the group (including coverage arising from all premiums within the contract boundary determined at that date applying paragraph 34) is one year or less.

While the PAA is primarily for groups of short-duration contracts, it is allowed whenever it provides a materially equivalent measure (in this chapter referred to as good approximation) to the GMA liability for remaining coverage (paragraph 53(a)), thus it is not able to differ materially. It is, however, qualified by paragraph 54 (see question 7.5).

Paragraph 53(b) allows the PAA to be used for groups of contracts with a coverage period of one year or less, regardless of whether it provides a good approximation. The length of the coverage period depends on the contract boundary (see question 7.8). Many non-life insurance contracts satisfy this criterion. However, longer-term annual renewable contracts may also satisfy this criterion, if the contract boundary lies at the next renewal date.

Use of the PAA is optional. The GMA can always be used, even where the PAA is allowed. The PAA was introduced mainly to provide a simplified approach for general insurance contracts and short-duration risk insurance more generally. It might be suitable for many single-premium contracts. It may also be suitable for regular-premium contracts, where each premium is commensurate with the risk for the corresponding period of coverage. For more complex contracts, it may not prove simpler in application than the GMA, particularly if the time value of money must be allowed for.

Another consideration is consistency. An entity writing general insurance contracts may prefer to go to some extra effort in testing if the PAA can approximate the GMA in order to use the PAA for as many contracts as possible. This might allow such an entity to use consistent reporting of the whole business and remove the additional burdens of measurement under the GMA in the pre-claims period, such as the more detailed disclosure requirements of the GMA. Conversely, an entity writing life insurance contracts may prefer...
to use the GMA, rather than the PAA, even for simpler contracts, for consistency with how most of its contracts will be measured and presented.

7.5. When is the PAA not allowed?

The PAA cannot be applied in circumstances outlined in paragraph 54 which states:
The criterion in paragraph 53(a) is not met if at the inception of the group an entity expects significant variability in the fulfilment cash flows that would affect the measurement of the liability for remaining coverage during the period before a claim is incurred. Variability in the fulfilment cash flows increases with, for example:

(a) the extent of future cash flows relating to any derivatives embedded in the contracts; and

(b) the length of the coverage period of the group of contracts.

The PAA may have a greater risk of not producing a reasonable approximation to the GMA in the following example scenarios, noting this is not intended to be an exhaustive list:

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Reasoning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patterns of the expected incurred claim costs and the release of the risk adjustment are significantly different from each other, during the coverage period.</td>
<td>The PAA approach reduces the liability for remaining coverage in line with the pattern of incurred claim costs while the GMA would consider the impact of both in the relevant building blocks potentially leading to significant differences in the value of the liability for remaining coverage under the PAA versus the GMA over the coverage period.</td>
</tr>
<tr>
<td>The pattern of expected incurred claim costs is highly uneven and the CSM is significant under the GMA.</td>
<td>The CSM is released in accordance to the insurance service provided which is based on coverage units for the duration of coverage. If the coverage provided by a contract is the same over the coverage period, then the CSM would be expected to be amortized evenly for each coverage period. For the PAA, an uneven pattern of expected incurred claims would result in an uneven pattern of premium allocated to each period. The size of the CSM would then determine the significance of this difference.</td>
</tr>
</tbody>
</table>
The longer the expected payout pattern is for the coverage and / or the higher the interest rate environment.

Significant variability in the cash flows may occur during the coverage period if the time value of money is a major component of the underlying building blocks of the GMA. For very long payout patterns, such as excess workers’ compensation coverage, even a small change in a low interest rate environment could significantly change the value of the liability for remaining coverage. In a high interest rate environment, interest rates tend to be more volatile, and discount can make up a significant portion of the liability for remaining coverage even for shorter tailed non-life business.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Implication</th>
</tr>
</thead>
<tbody>
<tr>
<td>In a high interest rate environment where there is no significant financing component and the premium is due within a year of providing the relevant coverage.</td>
<td>In this situation an entity is not required under the PAA to reflect the time value of money in the liability for remaining coverage but would be required to do so under the GMA.</td>
</tr>
<tr>
<td>In a high interest rate environment where there is significant financing component.</td>
<td>In this situation an entity is required under the PAA to reflect the time value of money in the liability for remaining coverage using a discount rate locked in at initial recognition. A high interest environment tends to be volatile and an entity that used the GMA without a locked in discount rate may produce a significantly different answer for the liability for remaining coverage than the PAA.</td>
</tr>
<tr>
<td>There is a significant investment, service or other non-insurance component to the contract, or there is a significant profit sharing component.</td>
<td>These are complications which the PAA was not designed to handle and where it might not approximate the GMA.</td>
</tr>
<tr>
<td>The cost of any embedded options or derivatives is significant</td>
<td>Paragraph 54 (a) of the standard tells us that increasing amounts of embedded derivatives is an example of where variability in the fulfilment cash flows could be significant.</td>
</tr>
<tr>
<td>Coverage is deferred</td>
<td>While the PAA might require the liability for remaining coverage to accrete interest, the</td>
</tr>
</tbody>
</table>
longer the deferral period the greater the mismatch is likely to occur between the underlying building blocks of the GMA and the PAA’s liability for remaining coverage. The GMA will continue to update expectations of future cash flows while the PAA will only adjust for changes in the timing for incurred claims in the coverage period per paragraph B127.

### Longer duration contracts generally

For many reasons already highlighted, the longer the contract the greater the variability can be in the projected fulfilment cash flows under the GMA.

### Situations where there can be significant changes in the initial “written” premium which could include:

- Cancellation of policies within the coverage period
- Lapses through non-payment of future premiums, when premium has not been paid upfront
- Contractual premium audits during the coverage period
- Reinstatement provisions that could result in additional future premium

Under the PAA, premium is allocated based on the passage of time or incurred claims if the expected pattern of release from risk is significantly different from the passage of time. It does not explicitly reflect cancellations or return of premium, nor future premium from reinstatements or other sources on an expected value basis. Paragraph B126 requires an entity to recognise revenue under the PAA by allocating “expected” premium receipts to each coverage period. No clarity is given on the measurement basis for “expected” premium receipts.

The GMA, on the other hand, reflects premium cash flows on an expected value basis, and changes in them during the coverage period for the liability for remaining coverage as expectations change.

### Contracts with level expected incurred claims and non-level indirect expenses

The PAA would allocate the premium evenly over the contract period while the GMA would recognise the non-level nature of the indirect expenses in the fulfilment cash flows.

7.6. For contracts whose coverage period is greater than 12 months in length, is it necessary to test whether the PAA is an approximation of the GMA?

The standard does not explicitly require a test to demonstrate that the PAA is an approximation of the GMA. However, relevant stakeholders, such as an entity’s auditors,
might expect the entity to justify its use for groups of contracts which contain contracts with more than 12 months coverage. The justification required depends on the circumstances, although paragraph 54 suggests that the criterion is evaluated only at inception looking at the measurement of the “liability for remaining coverage during the period before a claim is incurred”.

For single premium contracts that run for only a few months more than a year, it may be sufficient to demonstrate that there is no obvious reason why the PAA would not be a good approximation to the GMA over the coverage period.

In some simple circumstances, it may be possible to demonstrate mathematical equivalence between the PAA and the GMA. This may be the case, for example, for single premium contracts, if the expected incurred cost is level over the coverage period, the risk adjustment is a flat percentage of the future cash flows and the PAA reflects the time value of money.

For a longer term group of single premium contracts, it may be desirable to perform a few sample calculations on both bases, in order to confirm that they produce similar results for the liability for remaining coverage.

Where there are future premiums, or any other features that create a greater risk of not producing a reasonable approximation to the GMA (see question 7.5 above), it may be desirable to undertake more exhaustive testing. If this is unduly laborious, it may be an indication that the PAA is not appropriate for use.

If limited testing does not clearly indicate that the PAA is a good approximation, and PAA presentation is strongly preferred for such reasons as consistency with the rest of an entity's business, it may be necessary to undertake parallel calculations to confirm a reasonable approximation.

At adoption of IFRS 17 there may be more emphasis on testing approaches until familiarity amongst practitioners allows qualitative reasoning as a justification in certain cases.

7.7. When is a group of contracts recognised?

The recognition criteria for groups under the PAA are the same as for the GMA. Under paragraph 25 a group is recognised at the “earliest of the following:

a. the beginning of the coverage period of the group of contracts;

b. the date on which the first payment from a policyholder in the group becomes due; and

c. for a group of onerous contracts, when the group becomes onerous.”
The first criterion is consistent with how entities in some jurisdictions that write short duration contracts recognised contracts under local GAAPs and IFRS 4 prior to the effective date of IFRS 17. The second criterion would be triggered if any premium deposit, instalment or the full amount is due prior to the start of the coverage period.

7.8. What is the contract boundary?

The contract boundary is defined by paragraph 34, and discussed in Chapter 1 of this IAN.

The significance of the contract boundary in the context of the PAA lies in whether the contract has a coverage period of one year or less and is therefore automatically eligible for the PAA. For many general insurance contracts, neither insurer nor insured is obliged to renew, so the contract boundary is clear.

The situation is rather less clear for compulsory insurances, where the right of the insurer to set a premium that fully reflects the risk is compromised in certain jurisdictions.

In cases of doubt, the actuary may seek guidance from the entity’s technical accounting group to reach a consensus on the issue.

7.9. What is the initial measurement approach to the liability for remaining coverage?

The initial measurement under the PAA is set out in paragraph 55(a).

on initial recognition, the carrying amount of the liability is:

i.  the premiums, if any, received at initial recognition;

ii. minus any insurance acquisition cash flows at that date, unless the entity chooses to recognise the payments as an expense applying paragraph 59(a);

and

iii. plus or minus any amount arising from the derecognition at that date of the asset or liability recognised for insurance acquisition cash flows applying paragraph 27.

Under paragraph 59(a), if the coverage period is 12 months or less for each contract in the group at initial recognition the entity “may choose to recognise any insurance acquisition cash flows as expenses when it incurs those costs.” This may cause a material difference between the PAA and the GMA for the liability for remaining coverage which is why it is only permitted when the coverage period is less than 12 months for each contract in the group and the safe harbour election of the PAA can be made.

Onerous contract liabilities are discussed below (see question 7.14).

For general insurance business, on a single premium basis with the initial recognition when the premium is due, if the option in paragraph 59(a) is not taken, the overall effect is that of an unearned net premium. Instead of an initial unearned premium (UEP) equal to the written
premum, less an initial deferred acquisition cost equal to the deferrable acquisition costs (DAC), the initial UEP is effectively net of acquisition costs and there is no DAC asset.

While initially thought of as a UEP model, the PAA’s initial measurement criteria will not provide users of the financial statements with as much information as an unearned premium model grossed up for acquisition expenses and any premium owed. The PAA, through approximating the GMA of netting cash inflows and outflows, will not include the future inforce exposure by the amount of premium owed.

If the 59(a) option is taken, the initial UEP is equal to the premium received, but with no DAC. The effect of this is that the net liability is greater than under previous approaches by the amount of DAC that is not recognised.

This measurement approach does not capture any expectation of policy cancellations. If significant, policy cancellations on premiums paid could result in overstating the liability, or for contracts with a coverage period of greater than 12 months the use of the PAA may not be appropriate per the requirements of paragraph 54 of IFRS 17, which require that there not be an expectation of significant variability in the fulfilment cashflows that would affect the measurement of the liability for remaining coverage.

7.10. What is the subsequent measurement approach to the liability for remaining coverage?

The subsequent measurement under the PAA is also set out in paragraph 55(b) which states

at the end of each subsequent reporting period, the carrying amount of the liability is the carrying amount at the start of the reporting period:

(i) plus the premiums received in the period;
(ii) minus insurance acquisition cash flows; unless the entity chooses to recognise the payments as an expense applying paragraph 59(a);
(iii) plus any amounts relating to the amortisation of insurance acquisition cash flows recognised as an expense in the reporting period; unless the entity chooses to recognise insurance acquisition cash flows as an expense applying paragraph 59(a);
(iv) plus any adjustment to a financing component, applying paragraph 56;
(v) minus the amount recognised as insurance revenue for coverage provided in that period (see paragraph B126); and
(vi) minus any investment component paid or transferred to the liability for incurred claims.

As set out in B126, insurance contract revenue is recognised in each accounting period;

a) on the basis of the passage of time; but
b) if the expected pattern of release of risk during the coverage period differs significantly from the passage of time, then on the basis of the expected timing of incurred insurance service expenses.
Onerous contract liabilities and the circumstances under which the adjustment for the time value of money is required are discussed below (see questions 7.14 and 7.15). In practice, it is possible to turn this procedure around. In the absence of onerous contract liabilities, the PAA liability is the (present) value of future revenue (less future premiums). For single premium contracts where future revenue is pro-rata (see question 7.12 below) and discounting can be ignored, it may be easier to think in terms of UEP and calculate premium revenue as UEP at the start of the period, plus premiums received, minus UEP at the end of the period, similar to previous accounting practice.

7.11. What acquisition expenses should be used in the initial measurement?

Insurance acquisition cash flows is a term defined in Appendix A of IFRS 17 and is used in Paragraph 59(a). Their amount is an accounting determination but might include commissions, underwriting costs and contract setup expenses. For each group, all of these expenses must be directly attributable to the portfolio of insurance contracts to which the group belongs. For more details see chapter 4 on Estimates of Future Cash Flows.

7.12. How is revenue recognised for subsequent measurement periods?

Revenue recognition under the PAA is specified in paragraph B126.

…insurance revenue for the period is the amount of expected premium receipts (excluding any investment component and adjusted to reflect the time value of money and the effect of financial risk, if applicable, applying paragraph 56) allocated to the period. The entity shall allocate the expected premium receipts to each period of coverage:

a. on the basis of the passage of time; but

b. if the expected pattern of release of risk during the coverage period differs significantly from the passage of time, then on the basis of the expected timing of incurred insurance service expenses.

In practice, unless there are particular reasons to expect an uneven pattern, a good starting point might be an a priori pro rata assumption, modified to the extent demanded by credible experience. There is an inherent tension between using the largest possible portfolio to maximise credibility and smaller sub-portfolios to detect intra-portfolio variations. The best balance is a matter of judgement.

There is also the question of what does “differs significantly from the passage of time” mean? This is not defined by the standard although the term “significant” is often used in accounting frameworks to relate that something has more than a remote likelihood of causing a misstatement. This appears to be a lower threshold than something that is material, an item in accounting that would have an impact on the reader of the financial statement. Some may consider this a matter of accounting, rather than actuarial judgement, where the actuarial role is to provide the analysis on which that judgement can be based.

For example, the storm damage component of the premium for a home-owners policy in Queensland, Australia, where cyclone season typically falls between November and April, would differ significantly from the passage of time. But other perils insured under the policy
may have no such pattern, or even offsetting patterns. Other types of policies may have more subtle seasonal effects that would, due to the large number of policies sold, have a significant impact on revenue. For example, auto policies in the northern states of the US incur 72-74% of incurred losses over the first 9 months of a calendar year with the remaining 26-28% being incurred over the last quarter with the inclement winter months. This difference is subtle in terms of ultimate loss but might have a significant impact on the revenue recognition and bottom line profit of the company if the premium was recognised in line with the expected timing of incurred claims.

7.13. How should the liability for incurred claims be measured for contracts valued using the PAA?

The PAA is primarily a simplification of the measurement approach for the liability for remaining coverage under the GMA. However, there are a couple of minor simplifications that are permitted when measuring the claim liabilities, or the liability for incurred claims, if the contracts are initially measured under the PAA.

For contracts measured under the PAA, the liability for incurred claims is measured using the GMA with one potential modification; the entity is not required to adjust future cash flows for the time value of money and the effect of financial risk if those cash flows are expected to be paid or received in one year or less from the date the claims are incurred, as per Paragraph 59 (b).

The GMA allows for an entity to elect to lock-in interest rates for purposes of recognising finance income or expenses over the life of a contract, with changes in market rates going through Other Comprehensive Income (OCI). Based on paragraphs B133 and B72 (e) (iii), an entity that has used the PAA for measuring the liability for remaining coverage and wishes to lock-in discount rates shall do so based on the incurred date of the claim liabilities, and not the initial contract recognition date as per the GMA. For practical purposes of implementation, one way to do this is to lock-in a discount rate for each group of contracts based on the average accident date of a period (quarterly or annual). This could be justified if the average claim size is assumed to be uniformly distributed over the period.

7.14. When and how should an onerous contract liability be recognised?

Onerous contracts, in the context of the PAA, are the subject of paragraphs 18 and 57.

18 For contracts issued to which an entity applies the premium allocation approach (see paragraphs 53-59), the entity shall assume no contracts in the portfolio are onerous at initial recognition, unless facts and circumstances indicate otherwise. An entity shall assess whether contracts that are not onerous at initial recognition have no significant possibility of becoming onerous subsequently by assessing the likelihood of changes in applicable facts and circumstances.

57 If at any time during the coverage period, facts and circumstances indicate that a group of insurance contracts is onerous, an entity shall calculate the difference between:

(a) the carrying amount of the liability for remaining coverage determined applying paragraph 55; and

(b) the fulfilment cash flows that relate to remaining coverage of the group, applying paragraphs 33–37 and B36–B92. However, if, in applying
paragraph 59(b), the entity does not adjust the liability for incurred claims for the time value of money and the effect of financial risk, it shall not include in the fulfilment cash flows any such adjustment.

Note that, in the first instance, this test is applied to a group of contracts within a portfolio. Unless there are facts, or other circumstances, supporting the belief that the group of contracts is onerous, it is not necessary to look further at inception whether there is a group of onerous contracts. The latter half of paragraph 18 would indicate that the entity would still need to consider at inception whether to categorise the contracts in the portfolio as belonging to a group that has no significant possibility of becoming onerous in subsequent periods or not, as described in paragraphs 16 (b) and (c), based on the likelihood of the facts and circumstances changing during the coverage period.

Contracts may be onerous at issue or may become onerous later during the coverage period. The wording “facts or other circumstances” in this paragraph implies that an explicit test is not required. An explicit test is only needed when there is reason to believe that the portfolio containing the contracts may be onerous. This is clearly a matter of judgement. Possible indicators that may inform the decision to conduct testing include:

a. a group of contracts in the portfolio that are known to be onerous at initial recognition;
b. past losses in the portfolio;
c. aggressive underwriting or pricing;
d. unfavourable experience trends; and
e. unfavourable external conditions.

Groups of onerous contracts might also be identified by parallel GMA and PAA calculations. The excess of the GMA over the PAA liability for remaining coverage is recognised as a loss in P&L and increases the liability for remaining coverage. The GMA liability is discussed in chapters 2 to 6, but may be modified in accordance with paragraph 57(b) to exclude discounting, if the corresponding liability for incurred claims is (or would be) undiscounted in accordance with paragraph 59(b).

If at any time during the coverage period, facts and circumstances indicate that a group of insurance contracts is onerous, it is necessary to recalculate the difference between the GMA valuation of the liability for remaining coverage and the carrying amount (paragraph 57).

An onerous contract liability cannot arise for incurred claims, since these are not part of the liability for remaining coverage and are already valued at current fulfilment value under the GMA.

Onerous contracts are discussed further in chapter 5 on Unit of Account.

7.15. When is an adjustment made to the liability for remaining coverage for the time value of money required, and how is the adjustment made?

Adjustment for the time value of money is subject to paragraph 56. An adjustment is required where there is a “significant financing component” to contracts in a group. It is optional to adjust the liability for remaining coverage for the time value of money, if the time between providing the relevant portion of insurance coverage and the due date for the corresponding premium is expected to be 12 months or less.
The discount rates to be used are as determined at initial recognition of the contract. Interest rates are discussed further in chapter 3.

7.16. If the entity elects to use OCI for changes in interest rates in subsequent measurement periods for the liability for incurred claims, what is the locked-in discount?

If electing the OCI option to minimise the volatility from changes in interest rates in profit and loss, under the GMA the discount rate is locked-in at the start of the coverage period of the contract. The IASB has allowed for a practical difference with the PAA in paragraph B72 (e) (iii) whereby the discount rate is locked in based on the date incurred losses are recognised. Effectively, for practical purposes, for most portfolios of contracts this would imply the locked-in discount rate would be based on the average accident date of a period (e.g., quarterly or annual).

7.17. How is ceded reinsurance dealt with under the PAA?

Under paragraph 69, the PAA may be used for ceded reinsurance contracts, if they meet the same criteria as for direct insurance contracts. For proportional reinsurance, this may be the case if the direct contract is eligible for the PAA assuming the coverage is on a losses occurring basis, where the reinsurer covers losses that occur for a defined period of time under the contract. This is not necessarily true for proportional reinsurance on a policies or risks attaching basis, where the reinsurer covers losses arising from policies written over a defined period of time. For example, if these reinsurance contracts attach policies over a one-year period and the attaching policies are also written over a one-year period then the reinsurance contracts would have a coverage period of two years and would not be automatically eligible for PAA based on coverage of one year or less.

Conversely, non-proportional reinsurance is typically written on a loss occurring basis and may be eligible for the PAA, even if the underlying direct contracts are not, as long as the coverage period is one year or less. Some non-proportional reinsurance is unlikely to qualify for the PAA. For example, a catastrophe cover for tropical storms and other aggregate covers with a term in excess of one year may not qualify because the pattern of risk is likely to differ significantly from pro-rata over time. See earlier scenarios list in question 7.5.

7.18. How is assumed reinsurance dealt with under the PAA?

Paragraph 3 indicates that the standard applies to “insurance contracts, including reinsurance contracts” an entity issues. IFRS 17 does not explicitly differentiate between the treatment of an issued insurance contract and an issued reinsurance contract. Consequently, the PAA may be used if the reinsurance contract meets the requirements of paragraph 53. It is worth noting again that a risks attaching reinsurance contract, even with a contract length of one year, would not automatically be eligible for the PAA under paragraph 53(b) as the coverage provided would be in excess of one year but it might still be possible to apply PAA.

Under a non-proportional reinsurance treaty, particularly some catastrophe covers, such as those covering tropical storms, and other aggregate covers, the pattern of risk may differ significantly from pro-rata over time and therefore may not qualify for the PAA if the contracts have coverage periods in excess of one year.
7.19. When and how does an entity bifurcate non-insurance features under the PAA?

Non-insurance features are treated in the same way under the GMA and the PAA. Bifurcation is discussed in chapter 2. After bifurcation, the insurance part of the contract is valued in the same way as a stand-alone contract.

7.20. How are results presented under the PAA?

See chapter 15.

7.21. How is transition to the new standard treated if the entity will measure its liabilities using the PAA?

Transition is discussed in chapter 12. The PAA is not explicitly mentioned in IFRS 17 Appendix C, which covers transition.

It will usually be straightforward to apply the PAA retrospectively in accordance with paragraph C4 when the duration of most PAA contracts is one year or less, but the amount of effort may be dependent on internal data capture and systems. Retrospective implementation will require additional effort for contracts with coverage periods longer than one year.

7.22. How are contract modifications handled under the PAA?

Contract modifications are the subject of paragraphs 72 and 73.

Paragraph 72 indicates that when a contract is modified, “an entity shall derecognise the original contract and recognise the modified contract as a new contract”. It further notes that the “exercise of a right included in the terms of a contract is not a modification” but provides an exhaustive list of conditions under which the contract can be derecognized if, and only if, one or more of the conditions is met. These conditions include a modification that would have changed the group to which the contract would have been assigned at inception or a modification that would have changed a contract being accounted for under the PAA to no longer being eligible for that simplification.

Paragraph 73 is written in terms of the GMA, indicating that if none of the conditions are met under paragraph 72 the “entity shall treat changes in cash flows caused by contract modifications as changes in estimates of fulfilment cash flows by applying paragraphs 40-52”. Paragraphs 40-52 detail subsequent measurement under the GMA; therefore, for contracts where the PAA is applied, it would seem appropriate to proceed by applying the guidance for subsequent measurement under the PAA that is in paragraph 55(b).

Chapter 8 – Contracts with Participation Features and Other Variable Cash Flows

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality

8.A. What does this chapter address?

This Chapter considers the recognition, measurement and presentation of participating features, particularly in the case of contracts with direct participation features, as well as for other cash flows subject to the discretion of the insurer or linked to indices, including the criteria to be met for those classifications. The specific considerations on transition for participating contracts are covered in Chapter 12 – Transition.

8.B Which sections of IFRS 17 address this topic?

Paragraphs 45, 48(b), 71-72, 87, 89 111-113 and B27, B67-B71, B94, B96-B97, B101-B118 provide guidance on this topic.

8.C What other IAA documents are relevant to this topic?

None
General Issues

8.1. What are the types of participating contracts?

IFRS 17 defines different types of participation:

a) An Insurance contract with direct participation features (“Direct Participating Contract” or “DPC”). The contracts are defined in Appendix A and B101 and are measured using a variation of the approach used for insurance contracts without direct participation features.

b) Investment contracts with discretionary participating features. These contracts are defined in Appendix A and are measured under IFRS 17 rather than IFRS 9.

c) In addition, there are many different types of participating contracts in each jurisdiction that do not meet the criteria of a) or b). The actuaries in each jurisdiction will need to examine each type of insurance contract to see if it meets the requirements to be a Direct Participating Contract (DPC) (see 8.3). For example, some contracts may have discretionary payments that depend on the return on assets but do not meet either of the other requirements. Participating contracts that don’t meet all the requirements to be a DPC are measured in the same way as insurance contracts without direct participation features.

In assessing whether a contract is DPC, careful consideration must be made of the impact of guarantees both in terms of guaranteed returns and guaranteed benefit amounts as this will impact whether the requirement of B101(b) and B101(c) are met (B108). This means there may be groups of insurance contracts within the same product which fail to meet the requirements for direct participation, for example, where different levels of guarantees are chosen by different policyholders. It is possible that some contracts within a product could be measured as DPCs while others are measured as insurance contracts without direct participation features.

8.2. How is reinsurance handled for participating contracts?

Reinsurance contracts, issued or held, never meet the requirements to be a DPC and therefore are measured in the same way as insurance contracts without direct participation features (B109 and explained in BC248-BC249). See also Chapter 9 on Reinsurance.

Direct Participating Contracts

8.3. What is the definition of a Direct Participating Contract?

DPC are those contracts which meet the following criteria:

An insurance contract for which, at inception:

(a) the contractual terms specify that the policyholder participates in a share of a clearly identified pool of underlying items.
(b) the entity expects to pay to the *policyholder* an amount equal to a *substantial share* of the fair value returns on the *underlying items*; and

(c) the entity expects a *substantial proportion* of any change in the amounts to be paid to the *policyholder* to vary with the change in fair value of the *underlying items*.

For a DPC the definition of coverage period includes the period when the contract provides investment services as well as insurance services.

The standard defines “fair value” in several places, such as in the definition noted above. The fair value methodology is consistent with the fair value approach of IFRS 13. For further discussion on the measurement of fair value see the separate chapter – Chapter 10 Fair Value.

8.4. What does a clearly identified pool of underlying items mean?

The requirement is that underlying items are clearly identified by the contract. The definition of underlying items is given in Appendix A and expanded upon in B106:

> Items that determine some of the amounts payable to a policyholder. Underlying items can comprise any items; for example, a reference portfolio of assets, the net assets of the entity, or a specified subset of the net assets of the entity.

In order to meet the definition, B105 requires that the link to underlying items be “enforceable”. Enforceability (paragraph 2) is a matter of law. This can be contractual (contracts need not be written and can be implied by “an entity’s customary business practices”) and includes those imposed by external parties such as law or regulation. Enforceability cannot be assumed to apply for example across all products written by an entity.

8.5. What types of items can be included in the pool of underlying items?

B106 provides more information about the composition of underlying items. This could be a reference portfolio or the net assets of the entity. It does not need to be a separately defined fund belonging to the policyholder. The assets do not even need to be held by the entity e.g., the underlying items could be a defined external index.

8.6. *Can profits from portfolios of certain insurance contracts owned by a “participating” fund qualify as underlying items?*

This is likely to depend upon the nature of that income and is an issue that needs to be resolved between the reporting entity and its auditor.

8.7. What are some examples of situations that do not meet the requirements to be defined as underlying items?
A couple of examples are set out in B106 as not meeting the requirements to be defined as underlying items:

a) an entity can change the underlying items that determine the amount of the entity's obligation with retrospective effect; or

b) there are no underlying items identified, even if the policyholder could be provided with a return that generally reflects the entity's overall performance and expectations, or the performance and expectations of a subset of assets the entity holds. An example of such a return is a crediting rate or dividend payment set at the end of the period to which it relates. In this case, the obligation to the policyholder reflects the crediting rate or dividend amounts the entity has set, and does not reflect identified underlying items.

This latter example would exclude many traditional participating contracts from qualifying as DPCs.

8.8. What does a substantial share or substantial portion mean?

IFRS 17 does not specifically define what "substantial" means. In B101(b) the requirement is that the policyholder shares in a “substantial share of the fair value returns on the underlying items” and in B101(c) a “substantial proportion” of the amounts paid to policyholders to vary with the fair value of the underlying items.

This is further clarified in B107. The assessment is not made on a period by period basis but rather over the duration of the group of insurance contracts and

(ii) on a present value probability-weighted average basis, not a best or worst outcome basis.

8.9. What is the conceptual basis for measuring DPCs?

B104 explains that for a DPC, the entity's obligation to the policyholder is the net of:

(a) the obligation to pay the policyholder an amount equal to the fair value of the underlying items; and

(b) a variable fee

Further this variable fee is made up of two components:

(i) the entity's share of the fair value of the underlying items; less

(ii) fulfilment cash flows that do not vary based on the returns on underlying items.

So DPCs create:

an obligation to pay policyholders an amount equal in value to specified underlying items, minus a variable fee for service. That fee is an amount equal to the entity's share of the fair value of the underlying items minus any expected cash flows that do not vary directly with the underlying items.

138
The detail of this subsequent measurement is set out in B110 – B114 with further comments in BC238 – BC249.

Unlike insurance contracts without direct participation features, however, “all the adjustments are measured using current discount rates”.

All these different adjustments do not have to be identified separately (B114).

Note that the PAA, as described in Chapter 7, cannot apply when the insurance contracts meet the definition of a DPC.

8.10. How do DPCs work on initial recognition?

On initial recognition the approach for DPCs is identical to the approach used for insurance contracts without direct participation features. Fulfilment cash flows and a CSM are determined in the same manner as set out in paragraphs 32 - 39.

8.11. What discount rate is used for measurement?

The discount rate used for cashflows that vary based on the returns on underlying items are discussed in B74 – B77.

The standard allows for different approaches. The cash flows can either be discounted using rates that “reflect that variability”, or the cashflows themselves can be adjusted for that variability and discounted at a rate that reflects that adjustment. This is the case regardless of whether the entity actually holds the underlying items or not and whether the variation is set out in the contract terms or a matter of discretion.

Similarly, nominal cashflows (including the effect of inflation) are discounted using a discount rate that also includes the effect of inflation; and real cash flows (excluding the effect of inflation) are discounted at rates that exclude the effect of inflation.

Where minimum guarantees exist, the return is not solely dependent on the return on underlying items and the discount rate is adjusted to allow for the impact of the guarantee, even if the guarantee is lower than the expected return on the underlying items.

The standard does not require entities to divide cash flows into those that vary based on the return on underlying items and those that do not. If a split is not carried out, the discount rate reflects the impact on the combined cashflows. The standard cites both stochastic modelling techniques and risk-neutral approaches as appropriate approaches for doing this. (B77).

8.12. How do DPCs work on subsequent measurement?

DPCs are contracts where the entity's obligation to the policyholder is closely related to the underlying items. The entity's obligation to the policyholder is the net of (see paragraph B104):

(a) the obligation to pay the policyholder an amount equal to the fair value of the underlying items; and
(b) a variable fee that the entity will deduct from (a), comprising:
   (i) the entity’s share of the fair value of the underlying items; less
   (ii) fulfilment cash flows that do not vary based on the return on underlying items.

This relationship between the entity’s obligation to the policyholder and the underlying items requires the contractual service margin for DPCs being updated for more changes than for insurance contracts without direct participation features.

a) The CSM is additionally adjusted for the change in the entity's share of the fair value of the underlying items (see paragraphs 45(b) and B112), except to the extent that risk mitigation is applied (see paragraph B115 and question 8.15).

b) There is no explicit accretion of interest on the CSM, as this is implicit in (a).

c) The adjustment for changes in fulfilment cash flows that do not vary based on the returns on underlying items is measured using current discount rates (see paragraph B113(a)).

d) The adjustment for changes in fulfilment cash flows that do not vary based on the returns on underlying items includes the change in the effect of the time value of money and financial risks not arising from the underlying items (see paragraph B113(b)), except to the extent that risk mitigation is applied (see paragraph B115 and question 8.15).

e) Please also note that coverage for investment-related services is included, in addition to coverage for insured events, in the determination of coverage units when releasing the CSM (following the proposed amendments through the [2018] annual improvement cycle).

8.13. What discount rate is used for DPCs on subsequent measurement?

When making adjustments to the CSM for DPCs, all changes are determined using current discount rates. This applies to the entity’s share of the change in the underlying items and also changes in estimates of the fulfilment cash flows (B113). No locked-in interest rate is used.

8.14. What cash flows adjust the CSM in a given period for DPCs?

Changes in the value of the obligation to pay the policyholder an amount equal to the fair value of the underlying items (paragraph B104(a)) do not adjust the contractual service margin as they do not relate to future service (B111).

Changes in the entity’s share (paragraph B104(b)(i)) adjust the CSM as they do relate to future service (B112).

Changes in the fulfilment cash flows that do not vary based on the returns on underlying items (paragraph B104(b)(ii)) consist of two categories (B113). Taking the second first (B113(b)): 
the change in the effect of the time value of money and financial risks not arising from
the underlying items; for example, the effect of financial guarantees. These relate to
future service and, applying paragraph 45(c), adjust the contractual service margin...

In B113(a) all other changes in estimates of the fulfilment cash flows apart from those in
(b) are treated in the same manner as insurance contracts without direct participation
features and hence

an entity shall apply paragraphs B96–B97, consistent with insurance contracts without
direct participation features, to determine to what extent they relate to future service
and, applying paragraph 45(c), adjust the contractual service margin.

8.15. How does risk mitigation such as hedging impact the measurement of DPCs?

If risk mitigation is used then, for DPCs, the entity can choose to put some or all of the
changes in the effect of financial risk in the entity’s share of the underlying items
component of the variable fee (B113(b)) through the CSM. This is to remove accounting
mismatches.

This would for example allow the change in the fair value movement in derivatives which
goes through P&L to be offset by the equivalent fair value movement in liabilities through
P&L, as opposed to the liability impact being spread through the CSM (B115).

There are requirements to do this. These are set out in B116.

“an entity must have a previously documented risk-management objective and strategy for
using derivatives to mitigate financial risk arising from the insurance contracts and, in applying
that objective and strategy:

a) the entity uses a derivative to mitigate the financial risk arising from the insurance
contracts.

b) an economic offset exists between the insurance contracts and the derivative, i.e.,
the values of the insurance contracts and the derivative generally move in
opposite directions because they respond in a similar way to the changes in the
risk being mitigated. An entity shall not consider accounting measurement
differences in assessing the economic offset.

c) credit risk does not dominate the economic offset.”

This means the risk mitigation cashflows used in the fulfilment cashflows may need to be
allocated to each group and applied consistently in each reporting period (B117).

Finally, if the conditions required to use this approach are no longer met then the approach
cannot be used from that date, however previous periods are not adjusted retrospectively
(B118).
8.16. What happens when a DPC is modified?

If the terms of a contract are changed so that the insurance contract no longer meets the requirements for direct participation or vice versa (paragraph 72), the original contract is derecognised and a new contract recognised based on the modified terms. See Chapter 14 “Contract Modifications and Derecognition” for further details on contract modification.

8.17. Are there any special requirements for a DPC on transition?

There are specific requirements for DPC on transition. Some of the requirements differ from insurance contracts without direct participation features. See Chapter 12 – Transition for further details on transition requirements.

Investment Contracts with Discretionary Participating Features

8.18. What is the definition of an investment contract with a discretionary participating feature?

A financial instrument that provides a particular investor with the contractual right to receive, as a supplement to an amount not subject to the discretion of the issuer, additional amounts:

- that are expected to be a significant portion of the total contractual benefits;
- the timing or amount of which are contractually at the discretion of the issuer; and
- that are contractually based on:
  - the returns on a specified pool of contracts or a specified type of contract;
  - realised and/or unrealised investment returns on a specified pool of assets held by the issuer; or
  - the profit or loss of the entity or fund that issues the contract.

The treatment of these contracts is covered in paragraph 71 and B27(a) confirms that these contracts, although not insurance contracts, are in scope of IFRS 17 “ provided they are issued by an entity that also issues insurance contracts ”.

8.19. What are some examples of investment contracts discretionary cash flows?

One common example would be discretionary interest payments on a savings-type product.

8.20 How are Investment Contracts with DPF measured?

Investment Contracts with DPF are subject to the same measurement considerations as direct participating contracts - refer to questions 8.3 to 8.17.

Other Participating Contracts

8.21. What are some other types of participating contracts?
Traditional participating contracts where dividends (bonuses) are declared annually after completion of the year, not based directly on the return on a specified pool of underlying assets, are the most common type of contract that may fit here. For example, where there is no enforceable sharing mechanism specified for the participating contracts in question, so the dividend (bonus) can be adjusted to support performance on other contracts, or where the dividend (bonus) does not only depend on changes in the underlying items but also is materially based on sharing of expense or mortality profits as well. There are, however, a great variety of such contracts worldwide so each actuary needs to look at the particular contract under consideration to determine whether it meets the requirements to be a Direct Participating Contract.

8.22. How are cash flows on those contracts measured?

Many insurance contracts exist where there is an element of discretion (either in timing or amount) over the amounts paid to policyholders. Many of these will not meet the requirements for direct participation and hence are measured using the general measurement approach.

For these contracts (without direct participation features), expected discretionary payments are cash flows directly related to fulfilment of the contract and included within the contract boundary (B65). Any change in the discretionary element paid to policyholders that relates to future service adjusts the CSM. In order to assess if such a change has arisen an expected basis for these discretionary payments is included in the fulfilment cashflows at inception. The CSM is then adjusted for deviations from these expected cashflows (B98) subject to the following.

- Changes in these payments can arise as a result of changes in financial risk (these do not adjust the CSM) on those payments and “discretionary changes to that commitment” (adjust the CSM) (B99).

- If it is not possible to separate the commitment at inception and the discretionary element then the commitment is defined “to be the return implicit in the estimate of the fulfilment cash flows at inception of the contract, updated to reflect current assumptions that relate to financial risk”. (B100, BC237).

For some types of contracts, amounts may have accumulated over many decades in participating funds. The ownership of these funds may not be clear cut between shareholders and policyholders. If difficult judgements with unusual levels of uncertainty are required, this would require suitable disclosure.

When Cash Flows in one group (either Direct Participating or not) are impacted by cash flows in another group

8.23. In what circumstances are cash flows in one group considered to be impacted by cash flows in another group?
IFRS 17 recognises that sharing between groups of policyholders arises and has a section on “Contracts with cash flows that affect or are affected by cash flows to policyholders of other contracts” (B67 – B71).

This is limited to the sharing that arises from policyholders sharing in the returns on underlying items with other policyholders, including guaranteed payments either to that policyholder or the other policyholders. The basis for conclusions explains that this is a subset of the effect referred to as “mutualisation” (BC171) and that IFRS 17 only refers to this specific type of sharing, and other types such as “the effects of specific contractual terms to general risk diversification” are not included in the scope of “sharing.” The sharing will normally go both ways, so if a group of policyholders shares profits with another group but the second group does not share profits in reverse, this is not the mutualisation case being considered.

Payments and sharing of returns between existing groups of policyholders can be to current or future policyholders (B68(a)) recognising the fact that sharing mechanisms smooth payments over time and it is not possible to determine when or to whom payments will be made at any one point in time.

The important point is not to double count any impacts i.e., payments that have been included in the cash flows of one group are not included again in the cash flows of another.

As in other areas, IFRS 17 does not prescribe the approach to allow for the benefit / impact of this sharing. Different practical approaches are allowed. IFRS 17 does recognise that this practical approach may be at a higher level of aggregation than the individual groups of contracts. If this is the case, then a systematic and rational approach is used to allocate the effect of the change in underlying items to individual groups of contracts. Groups of contracts are still subject to the annual grouping requirement, just as contracts with no such sharing mechanism.

These fulfilment cash flows in a group of contracts may include payments expected to be made to current policyholders in other groups or to future policyholders. IFRS 17 does allow an approach where a liability for all such payments to be recognised and measured at an aggregate level with no allocation to specific groups (B71).

8.24 What are examples of situations in which cash flows in one group are impacted by cash flows in another group?

If profit sharing exists between two different groups, B69 explains the treatment. This is a very simple example. The first has a guarantee giving rise to fulfilment cashflows of 100. The second actually supports this guarantee. Without supporting the guarantee its share of the underlying items would be 350. When it provides support to the other group the share falls to 250 (350 – 100). Under IFRS 17 the fulfilment cashflows of the group providing the support reflect the full 350 i.e., including the 100, and the other group, which receives the support, excludes the 100 in relation to the guaranteed amount. This may represent a
Mutual Insurance Companies

8.25. Are there any special rules for mutual insurance companies?

The precise nature of mutuals varies widely. For all mutuals, in some manner policyholders, or subsets of policyholders, will also own the company i.e., “most of the residual interest of the entity is due to a policyholder and not a shareholder” (BC265).

The treatment will depend on the exact facts and circumstances of the mutual in question. Mutual insurers are, however, a specific case of mutualisation. Significant sharing exists between different groups of policyholders. In fact, policyholders, or a subset of policyholders will have rights to some, if not all, of the profits of the company.

This means that some policyholders will have two identities. The first a policyholder of the mutual insurer / entity, the second an owner of the mutual insurance company. These two roles are considered separately (B16).

Mutual insurers and the specific considerations for a mutual insurance company are considered further in the Basis for Conclusions (BC264 – BC269).

As some or all of the policyholders share in the residual interest, this means that residual interest payments to policyholders form part of the fulfilment cash flows regardless of whether those payments are expected to be made to current or future policyholders.

Thus, the fulfilment cash flows of an insurer that is a mutual entity generally include the rights of policyholders to the whole of any surplus of assets over liabilities. This means that, for an insurer that is a mutual entity, there should, in principle, normally be no equity remaining and no net comprehensive income reported in any accounting period (BC265).

This can give rise to accounting mismatches between the measurement of insurance contracts, measured at current value using fair value information, and the measurement of other net assets, not required to be measured at fair value, of the mutual insurance company. The other assets may be required to be measured on a basis giving rise to a value lower than fair value (BC266).

This means that liabilities on the balance sheet may be higher than recognised assets, even though they are solvent for regulatory purposes and therefore are shown to have no equity rather than negative equity (BC267).
Comparability across the entire insurance industry is important, irrespective of the nature of the insurance entity. To allow for the specific nature of mutual insurers, under IFRS 17 those mutual insurers can distinguish between (BC269):

(a) in the statement of financial position, the liability attributable to policyholders in their capacity as policyholders from the liability attributable to policyholders with the most residual interest in the entity; and

(b) in the statement(s) of financial performance, the income or expenses attributable to policyholders in their capacity as policyholders before determination of the amounts attributable to policyholders with the most residual interest in the entity.

8.26. When are any ownership rights of a policyholder in the mutual insurance company measured?

Ownership rights of a policyholder in a mutual insurance company may or may not be specifically measured depending on the jurisdiction, the type of company and the terms of a contract. The actuary may need to discuss the treatment to be used with his principal and the company’s auditors to agree a treatment for the company.

8.27. Is it possible for a mutual insurance company to have equity?

This is a controversial question. In BC265 it is implied that the IASB believes that normally mutual insurers will have no equity. This statement is not guidance, however, and it leaves open the possibility for exceptions. Discussions in the industry have disagreed that there is no equity on a variety of grounds depending on, among other items, the exact terms of the contract and regulatory requirements to hold capital.

The OCI Option

8.28. What is the OCI option?

Under IFRS 17 the insurance finance income or expenses comprises the change in the carrying amount of the group of insurance contracts arising from (paragraph 87):

a. the effect of the time value of money and changes in the time value of money; and

b. the effect of financial risk and changes in financial risk; but

c. excluding any such changes for groups of insurance contracts with direct participation features that would adjust the contractual service margin but do not do so when applying paragraphs 45(b)(ii), 45(b)(iii), 45(c)(ii) or 45(c)(iii). These are included in insurance service expenses.

An entity can make an accounting policy choice between including the full amount of the insurance finance income or expense in P&L or disaggregating this amount between P&L
and other comprehensive income (OCI) using a systematic allocation of the expected total insurance finance income or expenses over the duration of the group of contracts for contracts without direct participation features (paragraph 88).

For DPC the disaggregation is different. The disaggregation eliminates accounting mismatches with income or expenses included in profit or loss on the underlying items held (paragraph 89).

In both cases the balance of the amount included in P&L on disaggregation and the total amount of insurance finance income or expenses in the period is included in OCI (paragraph 90). The accounting policy choice as whether to disaggregate insurance finance income or expenses is made at the portfolio of insurance contracts level and is made in conjunction with an assessment of the treatment of the portfolio of assets (B129).

Changes in assumptions that relate to financial risk are included in insurance finance income or expenses. Inflation can be a financial or non-financial assumption. It depends on the nature of the inflation and how it is used (B128):

a. assumptions about inflation based on an index of prices or rates or on prices of assets with inflation-linked returns are assumptions that relate to financial risk;

b. assumptions about inflation based on an entity's expectation of specific price changes are not assumptions that relate to financial risk.

8.29. How does the OCI option apply to DPCs?

If an entity chooses to disaggregate insurance finance income or expenses for DPCs in the P&L the insurance finance income or expenses on the liabilities is equal and opposite to the income or expenses included in profit or loss for the underlying items resulting in “the net of the two separately presented items being nil” (B134).

If contracts no longer qualify for direct participation in some periods then the amount accumulated in OCI is included as a reclassification adjustment in P&L (This is based on the amount previously included and is not recalculated for the approach now applying, or the new assumptions B136).

i. if the entity had previously applied paragraph 88(b)—the entity shall include in profit or loss the accumulated amount included in other comprehensive income before the change as if the entity were continuing the approach in paragraph 88(b) based on the assumptions that applied immediately before the change; and

ii. if the entity had previously applied paragraph 89(b)—the entity shall include in profit or loss the accumulated amount included in other comprehensive income before the change as if the entity were continuing the approach in paragraph 89(b) based on the assumptions that applied immediately before the change.
No restatement of prior periods is required (B135).

8.30. How does the OCI option apply for other participating contracts?

For contracts with discretionary features for which changes in assumptions that relate to financial risk have a substantial effect on the amounts paid to the policyholder but which are not directly participating, the disaggregation is based on a systematic allocation of the expected total finance income or expenses over the duration of the group of insurance contracts. The systematic allocation is based on characteristics of the contracts, without reference to factors that do not affect the cash flows expected to arise under the contracts i.e., if expected recognised returns on assets do not affect the cash flows of the contracts in the group, the impact of those returns is excluded (see B132(a)).

The systematic allocations are also such that over the duration of the groups of contracts that total amount recognised in OCI is zero. This means that when a contact matures the carrying amount of the group of contracts is equal to the amount measured using the systematic allocation (B130).

The systematic allocation of the future cashflows can be determined in one of two ways:

(i) using a rate that allocates the remaining revised expected finance income or expenses over the remaining duration of the group of contracts at a constant rate; or

(ii) for contracts that use a crediting rate to determine amounts due to the policyholders—using an allocation that is based on the amounts credited in the period and expected to be credited in future periods.

The effective yield approach is defined in the illustrative examples (IE 159):

Applying paragraph B132(a)(i), the entity uses a rate that allocates the remaining revised expected finance income or expenses over the remaining duration of the group of contracts at a constant rate (an ‘effective yield approach’). The effective yield approach is not the same as the effective interest method as defined in IFRS 9 Financial Instruments.

If the financial assumptions remain the same through the years (i.e., no changes related to future cash flows), the calculated effective yield will remain the same. However, if the financial assumptions change a revised effective yield will need to be calculated. The amount going through the insurance finance income/expense in the P&L will be calculated using this effective yield rather than the initial discount rate. The difference between this and the total impact will go through OCI.

The second of these is the crediting rate approach and is defined in the illustrative examples (IE 165):
Applying paragraph B132(a)(ii), the entity uses an allocation based on the amounts credited in the period and expected to be credited in future periods (a ‘projected crediting rate approach’). In addition, applying paragraph B130(b), the entity needs to ensure that the allocation results in the amounts recognised in other comprehensive income over the duration of the group of contracts totalling to zero. In order to do so, the entity calculates a series of discount rates applicable to each reporting period which, when applied to the initial carrying amount of the liability equals the estimate of future cash flows. This series of discount rates is calculated by multiplying the expected crediting rates in each period by a constant factor (K).

Using the crediting rate approach requires at least the following steps:

1. Calculate the fair value of liabilities on current assumptions (in our example they increase when interest rates fall).
2. Solve for rates which “amortise” the difference between the new value and the original estimate, in proportion to how interest is credited.
3. This scaling factor then scales the future outstanding crediting rates up through time. This results in the movements on the liability side closely matching the movements on the asset side.
4. In all cases the OCI balance must be re-spread when conditions change, so that the outstanding OCI balance at the end is zero.

For the risk adjustment, if the risk adjustment is also disaggregated, the systematic allocation used is consistent with the allocation of the future cashflows.

For the CSM, the systematic allocation uses the discount rate used to accrete interest (locked-in rate) (B132).

Presentation and Disclosures

8.31. Are there any differences with respect to presentation for DPCs?

There are no specific presentation requirements for DPCs. See Chapter 15 for further details on presentation requirements.

8.32. Are there any additional disclosures required for DPCs?

For disclosures, an entity is required to explain the relationship between insurance finance income or expenses and the investment return on its assets (paragraph 110).

- The composition of the underlying items and their fair value is also disclosed (paragraph 111).
If risk mitigation is used and the CSM is not adjusted for some changes in the fulfilment cashflows the impact of this on the CSM is disclosed (paragraph 112).

If the basis for disaggregation of insurance finance income or expenses is changed then the period when the change occurred, the reason, any adjustments as a result and the carrying amount of the contracts to which the change applied are disclosed (paragraph 113).

Chapter 9 – Reinsurance

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality

9.A. What does this chapter address?

This chapter provides background and suggested practice on the treatment of reinsurance under IFRS 17. The note covers both reinsurance ceded (referred to as reinsurance “held” in IFRS 17) and reinsurance assumed (referred to as reinsurance “issued” in IFRS 17). As noted in paragraph 3, IFRS 17 is applicable to both reinsurance contracts held, and reinsurance contracts issued. For consistency with IFRS 17 terminology, reinsurance “held” and “issued” will be used in this note. Retrocession contracts are included in the definition of reinsurance contracts.

It is not applicable to reinsurance contracts that are considered to be Financial Instruments under IFRS.

9.B. Which sections of IFRS 17 address this topic?

As noted in paragraph 4, all references in IFRS 17 that refer to insurance contracts also apply to reinsurance contracts held unless otherwise indicated by specific reference to reinsurance issued or as specified in paragraphs 60-70 for reinsurance held.

9.C. What other IAA documents are relevant to this topic?

None
9.1. When is IFRS 17 used to account for reinsurance contracts?

A reinsurance contract is an insurance contract where one entity (the reinsurer) takes on all or part of the insurance risks issued by another entity. When an entity sends risks to another entity it is known as reinsurance ceded. When an entity receives risks from another entity it is known as reinsurance assumed. Where there is significant insurance risk transfer, the reinsurance contract is considered as an insurance contract under IFRS, and IFRS 17 is applicable (paragraph 3). This applies to both reinsurance held (the IFRS 17 terminology for a reinsurance ceded contract) and reinsurance issued (the IFRS 17 terminology for a reinsurance assumed contract).

IFRS outlines the criteria to determine whether there is significant insurance risk transfer under the contract (see question 9.2 below). Where a contract fails these criteria, IFRS 17 does not apply, and the reinsurance is treated as a financial instrument.

9.2. What constitutes significant insurance risk transfer for reinsurance?

To determine if IFRS 17 is applicable, for each reinsurance transaction that a company has in place, an assessment needs to be made as to whether there is significant insurance risk transfer under the contract. The criteria are covered in detail in paragraphs B7-B23. See Chapter 1 – classification of contracts.

Under IFRS, an insurance contract is one under which one party accepts significant insurance risk, other than financial risk, from another party by agreeing to compensate the other party if a specified uncertain future event (the insured event) adversely affects the other party.

Under IFRS, the insurance risk is significant if, and only if, an insured event could cause the insurer to pay additional benefits that are significant in any single scenario, excluding scenarios that lack commercial substance (i.e., have no discernible effect on the economics of the transaction). IFRS specifically says this condition may be met even if the insured event is extremely unlikely or even if the expected (i.e., probability-weighted) present value of contingent cash flows is a small proportion of the expected present value of all the remaining contractual cash flows.

For reinsurance, there are two specific exceptions to the above general principles:

- Lapse, persistency or expense risk would not normally meet the criteria for insurance risk outlined above as, under paragraph B14, because the resulting variability in the payment to the is not contingent on an uncertain future event that adversely affects the policyholder. However, where risk that does not adversely affect the policyholder is mitigated by an entity by using a second contract to transfer some of all of these risks to another party, that party is exposed to insurance risk (paragraph B15). Therefore, a reinsurance contract that satisfies this criterion meets the definition of an insurance contract and hence is a reinsurance contract under IFRS 17. It should be recognised and measured as reinsurance issued and reinsurance held for the respective party.

- Even if a reinsurance contract does not expose the issuer of the contract to the possibility of a significant insurance loss, the contract is still deemed to transfer significant insurance risk if it transfers substantially all of the insurance risk relating to the reinsured portions of the underlying insurance contracts (paragraph B19).
Therefore, a reinsurance contract that meets this criteria can be considered as insurance contracts for both the entity issuing the contract and the entity that holds the reinsurance.

THE BALANCE OF THIS CHAPTER IS APPLICABLE ONLY TO REINSURANCE CLASSIFIED AS INSURANCE CONTRACTS UNDER IFRS

Reinsurance Held - (Questions 9.3 – 9.16)

9.3. How is reinsurance held presented in the IFRS statement of financial position and statement of financial performance?

Where an entity has entered into reinsurance contracts to cede insurance risk associated with underlying insurance contracts (either direct insurance contracts or reinsurance contracts issued), the reinsurance held contracts are recognised and presented on the balance sheet as groupings of reinsurance contracts held that are assets and groupings of reinsurance contracts held that are liabilities. This means that for the statement of financial position, the reinsurance held is shown separately from the underlying insurance contracts (paragraph 78). Similarly, for the statement of financial performance, the income and expense from reinsurance held are shown separately from the expenses and income of the underlying insurance contracts (paragraph 82).

9.4. Does reinsuring insurance contracts impact the recognition of the underlying insurance contracts?

No. Reinsurance does not impact the recognition of the underlying insurance contracts. As per paragraph 75, "when an entity buys reinsurance, it shall de-recognise the underlying insurance contract(s) when, and only when, the underlying insurance contract(s) is or are extinguished".

9.5. Does reinsuring insurance contracts impact the measurement of the underlying insurance contracts on the IFRS balance sheet?

No under IFRS 17, the valuation of insurance contracts issued by an entity is not impacted by entering into reinsurance contracts to mitigate risks in the contracts issued. The insurance contracts continue to be valued on a gross basis. Therefore, the estimates of future cash flows of a group of underlying insurance contracts would usually be the same regardless of whether there is reinsurance held associated with these obligations. This also applies to the entirety of the fulfilment cash flows, including the risk adjustment for non-financial risk, and the CSM.

It should be noted that an entity’s approach to diversifying its risk exposure, including potential use of reinsurance, may impact the gross risk adjustment. However, this would be an indirect impact based on the entity’s approach to using reinsurance generally to diversify risk, and not reflect a direct linkage for a specific reinsurance held treaty.

9.6. How are reinsurance contracts held measured?

The measurement of reinsurance held is represented by the fulfilment cash flows associated with the reinsurance held contract plus a CSM. The measurement value is
separately determined from the valuation of the fulfilment cash flows and CSM of the underlying gross insurance liabilities. See also questions 9.9 and 9.10.

While the valuation measurement follows the same General Measurement Approach as for insurance contracts generally, there are some key differences in the methodology.

With respect to the estimate of future cash flows, paragraph 63 requires consistency between the assumptions used in the measurement of the reinsurance contracts held and in the measurement of the underlying gross insurance liabilities (see question 9.9).

With respect to the risk adjustment, a different definition of the risk adjustment is used for reinsurance held that replaces the general definition used for insurance contracts (see question 9.9).

With respect to the CSM, there are specific additional considerations for reinsurance contracts held (see question 19.7.)

9.7. Does the asset or liability for reinsurance held have a CSM?

Assuming the PAA is not being used, a CSM is determined for reinsurance contracts held using a similar approach as for other insurance contracts. However, there is a key difference in that the CSM can both reduce the reinsurance held asset (i.e., present value of reimbursements from the reinsurance contract exceed the present value of reinsurance premiums) and therefore defer recognition of profit from the reinsurance contract, or increase the reinsurance held asset (i.e., present value of reinsurance premiums exceeds the present value of reimbursements from the reinsurance contract) and therefore defer recognition of losses from the reinsurance contract.

This means that the concept of an ‘onerous’ reinsurance held contract does not exist (see paragraphs 29 (b), 61 and 65). The rationale is that a net loss from the reinsurance contract would usually represent a commercial expense of purchasing reinsurance and would normally be spread over the period in which the service is received.

However, where there is a change in the fulfilment cash flows of a group of underlying insurance contracts that does not adjust the CSM for this group, the insurer similarly does not adjust the CSM on the reinsurance held asset for changes in fulfilment cash flows associated with these same underlying insurance contracts (see paragraph 66 (c) (ii)). This applies only for subsequent measurement, not for initial measurement.

This means that where an entity has transferred risk to a reinsurer, there is an attempt for subsequent measurement to create consistency in how changes in the fulfilment cash flows associated with the risks transferred is treated in the CSM of the reinsurance held and the gross insurance liabilities. However, there is no attempt to create similar consistency at initial measurement.

9.8. Would the future cash flow assumptions for business covered by reinsurance held be the same as the future cash flow assumptions used for the same business in the underlying insurance contract valuation?

Paragraph 63 states that ‘the entity shall use consistent assumptions to measure the estimates of the present value of the future cash flows for the group of reinsurance contracts
held and the estimates of the present value of the future cash flows for the group(s) of underlying insurance contracts.” This means that assumptions related to policyholder behaviour or insured decrements (e.g., mortality rates, morbidity rates, policyholder claims assumptions) would be consistent between the underlying insurance contract valuation and where these assumptions are used to help determine the value of the reinsurance held. Other assumptions, such as expenses may be different.

In addition, other variables and determinants of the cash flows, including the contract boundary, may be different depending on the terms of the reinsurance. See also question 9.11.

9.9. How is the reinsurance held risk adjustment for non-financial risk determined?

A specific definition for the determination of the risk adjustment for reinsurance contracts held is provided that replaces the general definition in paragraph 37 used for insurance and reinsurance contracts issued in the standard. Under the definition for reinsurance held, the quantum of the risk adjustment for non-financial risk represents the amount of risk being transferred by the holder of a group of reinsurance contracts to the issuer of those contracts (paragraph 64).

The risk adjustment for the reinsurance held can therefore conceptually be thought of as the difference in the risk position of the entity with (i.e., net position) and without (i.e., gross position) the reinsurance held. As a result, the appropriate risk adjustment for the reinsurance held could be determined based on the difference between these amounts.

For reinsurance held, because the risk adjustment for reinsurance held is defined based on the amount of risk transferred to the reinsurer, the risk adjustment for reinsurance held will normally create an asset. On this basis, where a reinsurance contract held is reported as an asset the risk adjustment will have the effect of increasing the value of the asset, and will decrease the liability value where the reinsurance contract held is reported as a liability.

9.10. How is counter party risk of non-performance by the issuer of reinsurance contracts reflected in reinsurance contracts held?

In determining the fulfillment cash flows, the estimates of future cash flows to be received for the reinsurance contracts held are reduced by an allowance for reinsurance counter party failure to fulfill the contractual obligations (paragraph 63). This allowance would reflect not only potential reinsurance counter party failure due to defaults (i.e., credit events), but would include allowances for disputes resulting in reduced payments as well reflecting the effects of collateral. Default allowances would normally reflect the current financial condition and credit standing of the reinsurance counter party, as well as the potential for these conditions to change over time. If the allowance for non-performance in the fulfillment cash flows is changed, then the change does not adjust the contractual service margin (paragraph 67).

With respect to the risk adjustment, the requirement in paragraph 64 that the risk adjustment for non-financial risk represents the amount of risk being transferred by the entity to the reinsurer has been interpreted two ways with respect to non-performance risk. One interpretation is that counter party risk is not considered in the risk adjustment as this is not a risk formally transferred by the contract. An alternative interpretation that has been put forward is that counter party risk is appropriate to consider in the risk adjustment since
this is a risk that, at an entity level, exists for the party with the reinsurance held as a result of entering the contract to transfer risk.

9.11. Would grouping of business for reinsurance held be the same as contract grouping used for the same business in the gross insurance liabilities?

The grouping for business covered by reinsurance held may be different than the contract grouping for the same underlying business in the gross insurance liabilities.

Under IFRS 17, contracts are normally grouped, although it is permissible to have one contract in a group. In addition, the general approach is that unless a contract contains components that would be within the scope of another standard if they were separate contracts, the contract is contemplated as the most basic unit of account.

A reinsurance contract is a single contract, even though it may consist of cessions of many underlying insurance contracts.

Because certain reinsurance contracts already aggregate risk and consolidate underlying contract exposures, it may in some circumstances make sense to make use of the permission to have one (reinsurance) contract in a group.

The grouping requirements for insurance contracts outlined in paragraphs 14 – 24 also apply for reinsurance, with the exception that for reinsurance contract held there is an additional paragraph, 61, to account for the fact that reinsurance contracts cannot be onerous. Paragraph 61 states that “An entity shall divide portfolios of reinsurance contracts held applying paragraphs 14 – 24, except that the reference to onerous contracts in those paragraphs shall be replaced with a reference to contracts on which there is a net gain on initial recognition. For some reinsurance contracts held, applying paragraphs 14 – 24 will result in a group that comprises a single contract”.

9.12. What are the considerations when a reinsurance held contract may cover multiple years of underlying insurance contracts or risk attachments?

For reinsurance held, a single reinsurance held contract may cover multiple years of underlying contract cessions or risk attachments. Some reinsurance held contracts, in addition to covering existing risks / cessions, are open to accepting future cessions / risk attachments. This leads to the question, when measuring the value of an existing group of reinsurance held contracts at a point of time T, what future cessions / risk attachments after time T are reflected in the modeling of the future cash flows in the fulfillment cash flows.

There are several relevant paragraphs in the standard.

Paragraph 33 states that “An entity shall include in the measurement of a group of insurance contracts all the future cash flows within the boundary of each contract in the group”.

Paragraph 34 states that “Cash Flows are within the boundary of an insurance contract if they arise from substantive rights and obligations that exist during the reporting period in which the entity can compel the policyholder to pay the premiums or in which the entity has a
A substantive obligation to provide services ends when:

a) the entity has the practical ability to reassess the risks of the particular policyholder and, as a result, can set a price or level of benefits that fully reflects those risks; or

b) both of the following criteria are satisfied: (i) The entity has the practical ability to reassess the risks of the portfolio of insurance contracts that contains the contract and, as a result, can set a price or level of benefits that fully reflects the risk of that portfolio; and (ii) the pricing of the premiums for coverage up to the date when the risks are assessed does not take into account the risks that relate to periods after the reassessment date.”

The above wording in paragraph 34 is written from the perspective of a directly written insurance contract and must be interpreted for reinsurance held contracts. An interpretation that has been put forward for reinsurance contracts held is that cash flows are within the contract boundary for a reinsurance held contract if they arise from substantive rights and obligations that exist during the reporting period in which the ceding entity is compelled to pay amounts to the reinsurer or in which the entity has a substantive right to receive services from the reinsurer.

The implications of the above paragraphs in the standard might best be given by examples.

Consider 2 possible non-proportionate reinsurance held contracts each, for the sake of simplicity, considered a separate “group” of 1 contract.

Contract A is a reinsurance contract held where existing risks are covered until they expire at guaranteed rates. The treaty is open to new risk attachments but the reinsurer and cedent can terminate the treaty accepting new risks at any time.

The implication is that at any valuation date T that falls within the contract boundary, the insurer would project future cash flows related to the existing risk attachments, and would not project future risk attachments since there is no contractual obligation from either party to continue to accept new risks into the treaty. At time T+1, the cash flows of the reinsurance contract held would include the projections of cash flows for all risk attachments up to time T+1 (i.e., risks that attach between T and T+1 would be included and reflected as changes in estimates of the fulfillment cash flows).

Contract B is a reinsurance contract held where existing risks are covered until they expire at guaranteed rates. The treaty is open to new risks at guaranteed rates for at least the next 3 years, after which the reinsurer can terminate accepting new risks.

The implication is that at any valuation date T that falls within the contract boundary, the insurer would project future cash flows related to the existing risk attachments, and would also project future risk attachments for risks for the next 3 years because the reinsurer has contractually agreed to accept those risks by locking in guaranteed rates. At time T+1, the cash flows of the reinsurance contract held would include the projections of cash flows for all risk attachments up to time T+1, including true up of cash flows for actual versus expected for risk attachments between T and T + 1, plus updated projected cash flows for future risk attachments for the next 2 years.
There are other implications to be considered.

- The future cash flows included may impact the ability to use the PAA. Where a reinsurance contract is intended to cover multiple years of cessions / risk attachments, it may prove more difficult to prove eligibility to apply the PAA for contracts where the coverage period for the underlying contract is only 1 year, but new risks attach after the inception date.

- The IFRS 17 application guidance states that, when determining the discount rates for initial recognition, “an entity may use weighted-average discount rates over the period that contracts in the group are issued, which applying paragraph 22 cannot exceed one year” [paragraph B73]. When a reinsurance contract covers multiple cession years and all cession years are considered as part of the same contract for purposes, the interpretation that discount rates may only take into account interest rates during the initial year that a contract is in-force may produce an economic mismatch when a reinsurance contract is open for multiple years and new cessions are added in subsequent years after the initial contract year.

- There are additional considerations related to the cash flows to include in the modelling for proportionate reinsurance contracts (see question 9.13)

9.13. Are there special considerations for the initial recognition of proportionate Reinsurance Held?

There are additional considerations related to proportionate reinsurance held contracts.

Paragraph 62 states that “Instead of applying paragraph 25, an entity shall recognize a group of reinsurance contracts held: (a) if the reinsurance contracts held provide proportionate coverage – at the beginning of the coverage period of the group of reinsurance contracts held or at the initial recognition of any underlying contract, whichever is later; and (b) in all other cases – from the beginning of the coverage period of the group of reinsurance contracts held.”

Two views on the meaning of Paragraph 62(a) for proportionate reinsurance have been put forward. The first interpretation is that the additional consideration that there is no recognition until at least the first underlying contract is recognised applies only to the initial recognition of the group of reinsurance held contracts. It does not impact which cash flows are modeled once the group of reinsurance held contracts is initially recognised – that is, all future cash flows expected to be within the contract boundary are modeled regardless of whether the underlying contracts have been recognised. The second interpretation assumes that this additional consideration is broader and means that only cash flows associated with underlying contracts that have been recognised are modeled (i.e., future cash flows associated with underlying cessions that have not yet been recognised are not modeled).

Under Paragraph 62(b), for non-proportionate reinsurance all future cash flows expected to be within the contract boundary are modeled without reference to the status of underlying contracts.
9.14. What is a proportionate reinsurance coverage?

Proportionate reinsurance is not a defined term in IFRS 17. In the Basis for conclusions, which is not a part of the standard, there is a reference to the distinction between proportionate versus non-proportionate reinsurance [paragraph BC304]. “In some cases, the reinsurance contract held covers the losses of separate contracts on a proportionate basis. In other cases, the reinsurance contract held covers aggregate losses from a group of underlying contracts that exceed a specified amount”.

9.15. Can the PAA be used for reinsurance contracts held?

Yes, reinsurance contracts held are eligible for the PAA provided they meet the criteria to use the approach (paragraph 69). The criteria to use the PAA, such as coverage period of the contracts in the group, need to reflect the contractual terms of the reinsurance contracts held in the group, and not the underlying insurance contracts.

9.16. Are there potential economic mismatches between the measurement of a reinsurance contract held and the measurement of associated underlying insurance?

There are several areas of possible economic mismatch.

For reinsurance contracts held, the contract boundary definition means that the measurement of reinsurance contracts held will typically extend to include cash flows associated with future projected cessions up to the point at which the reinsurance contract can be exited for new business. The valuation of underlying insurance contracts will not include any cash flows related to these future projected cessions, since the underlying insurance contracts are only valued as written. This creates a mismatch in terms of timing of recognition of cessions versus underlying contracts.

For underlying contracts, losses are recognised at inception when contracts are onerous at inception, whereas any offsetting net gain on related reinsurance contracts held will be reflected in the CSM and recognised over the lifetime of the reinsurance contract held. This can create a mismatch in terms of timing of profit and loss on contracts that may be economically linked (e.g., pricing of underlying contracts frequently reflects impact of associated reinsurance, particularly for proportionate coverages).

Underlying contracts may use the Variable Fee approach, while associated reinsurance held contracts are not eligible to use the Variable Fee approach. This can create measurement mismatches due to significant differences in treatment of investment related impacts.

Reinsurance Held and Reinsurance Issued (Questions 9.17 – 9.20)

9.17. Would the contract boundary used for reinsurance issued and reinsurance held for the same contract necessarily be the same?

The contract boundary would normally be the same for both parties. This is because the contract boundary is determined by looking at the substantive rights and obligations of both parties to the contract.
9.18. How are contractual options such as recapture, cancellation, or commutation treated in developing reinsurance cash flows?

The cash flows would reflect characteristics of the reinsurance contract. Reinsurance treaties may contain options that may be exercised at the discretion of the party holding or issuing the contract. The cash flows might assume that the entities issuing and holding the reinsurance contract each exercises its control over such options to its advantage taking into account any other considerations with respect to expected behaviour. Advantage would be determined based on the assumptions used in the valuation.

9.19. Can Reinsurance contracts qualify as insurance contracts with direct participation features?

Reinsurance contracts, including both reinsurance held and reinsurance issued cannot qualify as insurance contracts with direct participation features (paragraph B109). Therefore, they cannot use the CSM approach outlined for contracts with direct participation features.

9.20. How should continuation of a reinsurance contract past a contract boundary be treated?

Under IFRS 17, two fundamentally different approaches have been put forward for the situation where a reinsurance contract with a contract boundary is extended beyond the original boundary through the exercise of contractual terms – for example, continuation of a fully cancellable reinsurance treaty with guaranteed premiums past the cancellation exercise date which created the boundary. Under one approach, the continuation would extend the contract boundary of the original contract and the impact reflected as changes in the fulfillment cash flows of the contract. Under the second approach, the continuation would be treated as a new contract with a new contract boundary.

The treatment as a change in fulfillment cash flows of an existing contract is based on the following considerations:

- It is consistent with Paragraph B64 which states that “in determining the estimates of future cash flows at the end of a reporting period, an entity shall reassess the boundary of an insurance contract to include the effect of changes in circumstances on the entity’s substantive rights and obligations”.

- It is consistent with the approach outlined in paragraphs 72 and 73 for treatment of various forms of contract modifications. Under these paragraphs, such renewal impacts would not meet the threshold for recognition of a new contract and would be considered as changes in the estimates of fulfillment cash flows. Interpretation is based on the modification and derecognition paragraphs 72 and 73. Under paragraphs 72, there is the statement that “the exercise of a right included in the terms of a contract is not a modification”. As such, changes in cash flows due to exercise of contractual rights would be considered as changes in the estimates of fulfillment cash flows by applying paragraphs 40-52 and not a new contract event.

- While paragraph 35 states that “an entity shall not recognise as a liability or as an asset any amounts relating to expected premiums or expected claims outside the boundary...
of the insurance contract. Such amounts relate to future insurance contracts”, this requirement is interpreted to mean that such cash-flows are not currently considered, but such assessment is not permanent and can change as substantive rights and obligations change.

The treatment as a new contract is based on a stricter interpretation of the paragraph 35 statement that “an entity shall not recognize as a liability or as an asset any amounts relating to expected premiums or expected claims outside the boundary of the insurance contract. Such amounts relate to future insurance contracts”.

Reinsurance Issued (Questions 9.21 – 9.23)

9.21. How is reinsurance issued presented on the IFRS balance sheet?

Where an entity has entered into reinsurance contracts to assume risk and obligations, the value of these contracts is shown on the balance sheet as part of the insurance liabilities or assets, with contracts grouped into those that are assets, and those that are liabilities.

9.22. Are there special considerations for reinsurance issued liabilities?

In general, reinsurance issued business, once classified as insurance risk, is treated consistently in approach with all other gross insurance liabilities issued.

Data issues are frequently more prevalent for reinsurance issued business, particularly life reinsurance, than for underlying insurance business, as the reinsuring entity is further removed from the underlying risks than the ceding entity, and is reliant on the entity company for underlying data on insured risks. This means that there is frequently more use of approximations both in terms of data and modeling approach. It is important that actuaries performing valuations of reinsurance issued business understand the impact of approximations made and be able to assess their reasonableness.

9.23. What are the considerations when a reinsurance issued contract may cover multiple years of underlying insurance contracts or risk attachments?

For reinsurance issued, a single reinsurance held contract might cover multiple years of underlying contract cessions or risk attachments, so that in addition to covering existing risks / cessions, treaties might be open to accepting future cessions / risk attachments.

This leads to the question, when measuring the value of an existing group of reinsurance issued contracts at a point of time T, what future cessions / risk attachments after time T should be reflected in the modeling of the future cash flows in the fulfillment cash flows.

The considerations and relevant paragraphs in the standard are similar to reinsurance held as covered in question 9.12.

Other Questions
9.24. What additional explanations and disclosures may be included in the actuary’s report related to reinsurance?

The objective of additional disclosure requirements is to enable the Board and management to better understand the way in which the actuary has undertaken his or her work. Key elements of this related to reinsurance, may include:

- discussion of the impact of reinsurance as part of risk mitigation considerations to determine the company’s risk profile;
- discussion of any uncertainty in relation to recoverability of reinsured amounts;
- discussion of the insurer’s net risk profile and how this is appropriately reflected as the difference between the gross and reinsurance risk adjustments.
Section C – Uses of fair value measurement in IFRS 17

This section considers the use of the fair value measurement of insurance contracts for IFRS 17 including for business combinations or portfolio transfers and on transition if the fair value approach is chosen. This section comprises three chapters:

- Fair Value – Chapter 10
- Business Combinations and Portfolio Transfers - Chapter 11
- Transition – Chapter 12

Chapter 10 discusses the principles of how to determine the fair value of insurance contracts in the context of the more general guidance on fair value measurement found in IFRS 13 Fair Value Measurement and of common insurance industry practices.

Chapter 11 discusses the requirements under IFRS 17 when accounting for insurance contracts or liabilities for incurred claims acquired in a business combination or a portfolio transfer, and in particular the need to use the fair value of the contracts as the initial consideration.

Chapter 12 discusses the one-time event of presenting statements applying IFRS 17 for the first time a section for each of the three transition approaches described in IFRS 17 – the retrospective approach of IAS 8 and the alternative approaches introduced by IFRS 17, modified retrospective and fair value.
Chapter 10 – Fair Value

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality

10.A. What does this chapter address?

This Chapter considers the fair value measurement of contracts in IFRS 17 in the context of the more general guidance on fair value measurement found in IFRS 13 Fair Value Measurement and of common insurance industry practices.

10.B. Which sections of IFRS 17 address this topic?

Paragraphs 39 and B94 specify the use of fair value when contracts are acquired in a business combination. Paragraphs C5 and C20-24 discuss the use of fair value on transition to IFRS 17.

10.C. What other IAA documents are relevant to this topic?

Chapter 12 Transition.
10.1. When is fair value measurement applied to insurance contracts? 

In IFRS 17, fair value measurement is used:

(a) at initial recognition of contracts acquired in a business combination. The fair value is determined as of the date of the acquisition. See Chapter 11, and

(b) on transition to IFRS 17 when the fair value approach (paragraph C5b) is selected. The fair value is determined as at the transition date, which is usually the beginning of the period immediately preceding the date of initial application of IFRS 17. See Chapter 12.

For insurance contracts acquired in a business combination, IFRS 17 states that the fair value of the contracts is the consideration received for those contracts (paragraph B94). Business combinations may include other assets and liabilities, in which case the consideration received for the insurance contracts needs to be determined separately from other assets and liabilities acquired, and may exclude certain factors that might be considered in a business combination (see Question 10.4).

This Chapter addresses fair value measurement in the context of business combinations where the consideration received for the insurance contracts is estimated and in the context of transition to IFRS 17. This Chapter may also be useful in the context of contracts acquired in a transaction that does not form a business combination where the fair value of groups of contracts is used to allocate the total consideration for the entire block of contracts to the groups.

Fair value measurement is also used to measure embedded derivatives that are separated from insurance contracts and for financial instruments issued by insurers, which are not in the scope of IFRS 17. These applications of fair value measurement are not addressed in this Chapter.

10.2. What is the fair value of insurance contracts?

IFRS 17 does not provide guidance on determining the fair value of insurance contracts, except as noted below in relation to a demand deposit floor. IFRS 13 Fair Value Measurement provides guidance when other IFRSs require fair value measurement, with certain exceptions. Insurance contracts are not specifically excluded from the scope of IFRS 13, and consequently IFRS 13 is relevant to insurance contracts. IFRS 13 does not provide specific guidance on insurance contracts; hence the entity is left to consider how to apply the guidance in IFRS 13 to insurance contracts.

IFRS 13 defines fair value as:

“...the price that would be received to sell an asset or paid to transfer a liability in an orderly transaction between market participants at the measurement date.”
(paragraph 9 of IFRS 13)

17 The term “insurance contracts” as used in this Chapter includes all contracts in the scope of IFRS 17
A comprehensive discussion of IFRS 13 is beyond the scope of this Chapter. What follows are the relevant considerations of IFRS 13 as they apply to insurance contracts.

<tr>
<td>IFRS 13 has a number of disclosure requirements related to fair value measurement after initial recognition (paragraphs 91-99 of IFRS 13).</td>
<td>Fair value measurement of insurance contracts only takes place at an initial date (acquisition date or date of first reporting on transition), and therefore the disclosure requirements of paragraphs 91-99 of IFRS 13 may have limited applicability.</td>
</tr>
</tbody>
</table>

### 10.3. How is the fair value of insurance contracts calculated?

IFRS 13 does not prescribe a valuation technique. In the context of a business combination, the entity may have an analysis of value that can form the basis of the fair value measurement, perhaps requiring adjustment to be consistent with the objective of an exit price.

The application guidance in Appendix B of IFRS 13 provides information about other possible valuation techniques. Among them are present value techniques (paragraphs B12-B30 of IFRS 13) for the fair value measurement of a stream of cash flows. These techniques share many characteristics with the IFRS 17 guidance on measuring fulfilment cash flows (e.g., paragraph B23 of IFRS 13) and therefore are candidates for the estimation of fair value of insurance contracts under IFRS 17.

An approach to estimating fair value of a group of insurance contracts using a present value technique is to adjust the fulfilment cash flows of the group of insurance contracts in order to fulfil the objectives of IFRS 13. Adjustments to reflect the perspective of market participants (i.e., to move to an exit price) are discussed in Question 10.5.
IFRS 13 does not specify that a fair value estimate be before-tax or after-tax. However, there is a general admonition that valuations should be internally consistent, with specific mention that this general principle means that after-tax cash flows are discounted with an after-tax rate, and pre-tax cash flows are discounted with a pre-tax rate.

10.4. How would IFRS 13 Level 1 and 2 inputs (observable market information) be applied?

Market transactions involving insurance contracts may provide information about fair value, and the estimated fair value should be consistent with observable market information where available. However, it is unlikely that a direct relevant market price would be found. Furthermore, the transaction price at which a group of insurance contracts is exchanged may include factors (such as those in paragraph B4 of IFRS 13) that would be ignored for the purpose of estimating the fair value of a group of insurance contracts. Factors specific to insurance contracts that would be ignored include, for example:

- Expected profits/losses associated with cash flows beyond the boundaries of the insurance contracts,
- Expected profits/losses associated with investment/service components that will be recognized and measured separately from the group of insurance contracts, and
- Expense, tax or other synergies that a particular market participant might expect to realize, but that would not be generally available in the principal market.

Information that would be relevant, if reasonably available, might include:

- Market view of expected expenses associated with fulfilling the obligations of the insurance contracts in the group,
- Market view of the cost of risk associated with taking on the obligations of the insurance contracts in the group, and
- Market view of the cost of reinsurance that would be required to take on the obligations of the insurance contracts in the group.

IFRS 13 requires the entity to maximize the use of relevant observable inputs (paragraphs 3, 36, 61 & 67 of IFRS 13). However, an entity need not undertake exhaustive efforts to obtain information about market participant assumptions and may use information that is reasonably available (paragraph 89 of IFRS 13).

10.5. When using a present value approach, what adjustments would be made to fulfilment cash flows to satisfy the objectives of fair value measurement?
When using a present value approach, the fair value of a group of insurance contracts can be seen as the fulfilment cash flows adjusted to take into account the perspective of market participants (i.e., move to an exit price).

Possible adjustments that could be made include the following:

- The discount rates applied to the estimates of future cash flows (paragraph B14c of IFRS13) are increased to reflect the entity’s own credit risk (paragraph B13f of IFRS13).

- Where consistent with market practice, the discount rates applied to the estimates of future cash flows are adjusted to reflect the perspective of market participants on the liquidity characteristics of the group of insurance contracts.

- Where different from the entity’s view, projected expense cash flows reflect the market view of the expenses associated with fulfilling the obligations of the group of insurance contracts. For example, where consistent with market practice, expense cash flows are increased to cover a reasonable level of general expenses (i.e., expenses not directly attributed to the portfolio to which the group of insurance contracts belongs).

- Where different from the entity’s view, other assumptions used in cash flow projections are adjusted to reflect the market view. For most assumptions, the market view are likely to be the same as the entity’s view because the entity has the best information available and the fulfilment cash flows take into account all relevant available information. However, for assumptions that are not specific to the entity or its contracts (e.g., future population mortality improvement), the market view might differ from the entity’s view.

- Where different from the entity’s view, the risk adjustment for non-financial risk is adjusted to reflect a degree of risk aversion (paragraph B83b of IFRS 17) consistent with the market view.

- Where different from the entity’s view, the degree of diversification benefit (paragraph B83a of IFRS 17) included in the risk adjustment for non-financial risk is adjusted to be consistent with the market view. As noted in Question 10.2, the unit of account for fair value measurement under IFRS 17 is group of insurance contracts.

- Where consistent with market practice (and where not otherwise reflected in the estimate of fair value), the risk adjustment is increased to include the cost of capital or risks not covered in the fulfilment cash flows.

- Where consistent with market practice (and where not otherwise reflected in the estimate of fair value), the fair value is decreased to reflect expense, tax, or other synergies that would be available in the principal market.
Where not included in the other points above, the return that a market participant would require for undertaking the activity (see paragraph IFRS 13.41 and B31), which could be interpreted to include profit margins that a third party would require for providing services attached to the contract.

10.6. How do embedded values or appraisal values compare to fair values?

Embedded values or appraisal values are typically determined in the context of a transfer of liabilities together with supporting assets, and consider the present value of future expected profits less the cost of capital.

The fair value of insurance contracts under IFRS 17 is the fair value of the liabilities only, i.e., ignoring the supporting assets. Therefore, embedded / appraisal values will not be directly relevant to fair value measurement under IFRS 17 because they measure the profit expected from liabilities together with assets rather than the amount of assets that would be required to take over the obligations (liabilities) of the contracts.

However, embedded / appraisal value calculations might provide some context to help assess the market view of the degree of risk aversion, cost of capital, or other factors affecting fair value measurement (see Question 10.5). For example, a high hurdle rate for the present value of future profits is likely to suggest a high cost of capital.

10.7. Can a group of insurance contracts be onerous on acquisition?

A group of insurance contracts would be onerous if the fair value is less than the fulfilment cash flows. This may be unusual under the present value approach described in this Chapter, as most of the adjustments noted in Question 10.5 contribute to the fair value being higher than fulfilment cash flows. However, there may be circumstances in which market conditions conspire to make the fair value less than the fulfilment cash flows, so this possibility would not be disregarded.

10.8. Are there any special considerations for estimating the fair value of insurance contracts with direct or indirect participation features?

The general approach is the same as for contracts without participation features. Adjustments made to fulfilment cash flows (Question 10.5) would reflect the participation features of the insurance contracts. In particular, if discount rates applied to cash flows that vary based on the returns on underlying items have been adjusted to reflect that variability (paragraph B74b), the discount rates used for fair value measurement would be similarly adjusted.

Alternatively (equivalently), the fair value of a group of insurance contracts could be estimated as the fair value of the groups’ share of the underlying items with adjustments as needed to account for the non-participating features of the contracts in the group.

10.9. Are there any special considerations for estimating the fair value of reinsurance contracts?

The general approach is the same as for direct written contracts. The market for reinsurance contracts would be related to the market for the contracts that are reinsured, as transactions involving reinsurance contracts are usually part of transactions involving

171
the reinsured contracts. With this perspective, the fair value of a group of reinsurance contracts can be viewed as the amount that brings the fair value of the reinsured (underlying direct) contracts to the net fair value of the direct contracts combined with the reinsurance contracts. In other words, the fair value of a group of reinsurance contracts is the difference between the fair value of the underlying direct contracts (ignoring reinsurance) and the fair value of the underlying direct contracts combined with the reinsurance contracts.
Chapter 11 – Business Combinations and Portfolio Transfers

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality

11.A. What does this chapter address?

This Chapter considers the requirements under IFRS 17 when accounting for insurance contracts or liabilities for incurred claims acquired in a business combination or a portfolio transfer, and in particular the need to use the fair value of the contracts as the initial consideration. This Chapter considers the interaction between IFRS 17 and the more general guidance found in IFRS 3 Business Combinations and discusses aspects of business combinations, such as the determination of goodwill and the recognition of intangible assets

11.B. Which sections of IFRS 17 address this topic?

Paragraphs 39, 108, and B93 - 95 provide guidance on this topic. Paragraph B5 may be relevant. Appendix D delineates concomitant amendments to IFRS 3 Business Combinations.

11.C. What other IAA documents are relevant to this topic?

Chapter 10 Fair Value is directly relevant. Contracts acquired in a business combination or in a portfolio transfer are measured by approaches consistent with the approaches used by the acquiring entity.
11.1. What are the general requirements of IFRS 3 for accounting for a business combination?

IFRS 3.4 requires the acquisition method of accounting to be applied to business combinations within its scope. The acquisition method views a business combination from the perspective of the acquirer. The acquirer purchases the assets and assumes the obligations of the seller. The measurement of the acquirer's assets and liabilities that existed before the acquisition is not affected by the transaction.

IFRS 3.5 describes the acquisition method as comprising four steps:

- Identifying the acquirer,
- Determining the acquisition date,
- Recognising and measuring the identifiable assets acquired and the liabilities assumed,
- Recognising and measuring goodwill or a gain from a bargain purchase.

Identifying the acquirer and determining the acquisition date are sometimes complex matters that do not require actuarial expertise. These issues are not in the scope of this IAN. Guidance can be found in IFRS 3.7, which in turn refers to IFRS 10 Consolidated Financial Statements, and in IFRS 3, B13-B18.

This chapter is primarily concerned with step 3 as it relates to insurance contracts and for acquisitions that do not form a business combination. There are some paragraphs and an appendix that provide some information about the other aspects of steps 3 and 4 to help the actuary understand the broader context in which the measurement of insurance contracts assets and liabilities is taking place.

11.2. What are the requirements of IFRS 17 for insurance contracts acquired in a business combination or in a transfer of contracts that do not form a business?

IFRS 17 provides guidance on the treatment of contracts acquired in a business combination or in a transfer of contracts that do not form a business combination. The distinction between a business combination and a transfer of contracts that does not form a business is discussed below. The application of the broader, non-insurance specific, guidance relating to business combinations and other acquisitions of assets or liabilities is discussed further in later sections of this chapter. The insurance-specific guidance in IFRS 17 relates to determining the initial Contractual Service Margin (CSM) for acquired contracts. According to paragraphs B93-B95

- the recognition date of the acquired contracts is the date of the business combination or of the transfer
- the initial consideration received or paid for the contracts acquired is a proxy for the premiums received. The consideration excludes amounts paid for any other assets or liabilities acquired in the transaction. In a business combination, in many instances the initial consideration is the fair value of the contracts (see Chapter 15 - Fair Value)
- the CSM for acquired contracts is calculated using the consideration as a proxy for the premium paid or received on the acquisition date. In a business
combination, if the contracts are onerous, the difference between the consideration for the contracts and the fulfillment cash flows forms a loss component and is recognised as part of goodwill. If the transfer of contracts does not form a business combination, the entity records a loss in the current period for the difference and establishes a loss component for the contracts.

The implication of these paragraphs is that the general requirements of IFRS 17 apply to insurance or reinsurance contracts acquired in a business combination or a transfer and that the fair value of the contracts is used in the determination of goodwill in a business combination. The effect of this implication is that the entity examines contracts acquired in a business combination or a transfer to determine which are in the scope of IFRS 17, and then applies the guidance in IFRS 17 on measurement, presentation and disclosure to those contracts. There is not a presumption that a contract is insurance at the recognition date, even if it had been classified as insurance by the seller. For example, contracts that had been determined to be insurance contracts at the time that they originated, but, at the acquisition date, no longer transfer significant insurance risk, would not be in the scope of IFRS 17 for the purposes of the acquirer. See also Chapter 1—Classification of Contracts.

As noted, the consideration is used in determining the CSM for contacts that do not use the Premium Allocation Approach (PAA). For contacts that use the PAA, the consideration represents the remaining unallocated premium of the relevant contracts.

Liabilities for claims incurred on contracts issued by the acquired entity do not have a CSM. IFRS 17 is generally construed to mean that the acquisition of claims liabilities constitutes the issuance of a contract that transfers the risk of adverse development to the acquirer. In some cases, the fair value and the fulfillment cash flows do not differ. In these cases, there is no CSM. In other cases, the fair value exceeds the fulfillment cash flows. This difference can be viewed as the part of the consideration that compensates the acquirer for the service provided. Hence any positive difference between the fair value and the fulfillment cash flows of claims liabilities acquired in a business combination or in another transfer is deferred and released into income over the coverage period, i.e., the period over which the acquirer is obligated to adjudicate the claims.

It is possible that the fair value of acquired insurance contracts is less than the fulfillment value. This situation might occur, for example, if the market conditions were such that the market participants required a margin for risk and profit that was less than the entity's adjustment for risk. A contributing factor may be that the fact that a fair value considers the credit standing of the entity, whereas the fulfillment value does not. In this situation the acquired contracts are onerous. If the contracts are acquired as part of a business combination, there is a loss component but there is no effect on P&L because the amount by which the fulfillment value exceeds the fair value is considered in goodwill. If the acquisition of the contracts is not part of a business combination, the entity recognizes a loss for the difference and establishes a loss component, as it would for contracts it issues.

The guidance in IFRS 17 for acquired insurance and reinsurance contracts is consistent with the general guidance in IFRSs for business combinations. Most of the relevant guidance for business combinations is found in IFRS 3, Business Combinations (IFRS 3).
Additional relevant guidance is in IFRS 13 Fair Value Measurement (IFRS 13), in IAS 12 Income Taxes, and in IAS 38 Intangible Assets. The guidance in these IFRSs that may affect accounting for business combination or transfers is discussed further below.

11.3. What is a business combination and how does it differ from a transfer of insurance contracts?

IFRS 17 does not define the terms “business combination”. There is guidance for determining if a transaction is a business combination in IFRS 3, as discussed further below. For the purposes of this IAN, a transfer is a transaction involving contracts in the scope of IFRS 17 that may not constitute a business combination. Although not stated as such, the distinction likely makes no difference to the measurement of the assets or liabilities, but it may affect the goodwill and the tax accounting associated with the transaction.

11.4. What are the general requirements for determining if a transaction is a business combination?

IFRS 3 in effect defines a process that involves:

(a) Determining the nature of the transaction; i.e., determining whether it is a business combination or a different type of transaction,
   a) Applying the acquisition method of accounting to transactions that are business combinations
   b) Recognising and measuring the identifiable assets acquired and liabilities assumed
   c) Recognising and measuring goodwill or a gain from a bargain purchase.

The following questions expand on these topics and on related matters.

IFRS 3 defines a business combination as “A transaction or other event in which an acquirer obtains control of one or more businesses.” It goes on to state that transactions referred to as “true mergers” or “mergers of equals” are also business combinations. A “business” is an integrated set of activities and assets that is capable of being conducted and managed for the purpose of providing a return in the form of dividends, lower costs or other economic benefits directly to investors or their owners, members or participants. The “acquirer” is the entity that obtains control of the acquired. Appendix B of IFRS 3 provides further guidance on determining if the transaction constitutes the acquisition of a business and on identifying the acquirer.

For accounting purposes when there is a business combination, the “acquirer” is not always the entity which legally acquires the other entity. Under a “reverse acquisition”, the entity whose stock is being legally acquired is the “acquirer” for accounting purposes, while the entity which is legally the acquirer becomes the “acquired” for accounting purposes. For example, this can occur where a larger entity arranges to have itself bought by a smaller entity, perhaps due to a preference to utilize the common stock characteristics of the smaller entity. The actuary may want to rely on their principal’s accounting experts to determine who the acquirer and acquired entities are for accounting purposes.

11.5. What if the transaction is not a business combination?
IFRS 3 excludes from its scope the acquisition of an asset or a group of assets that does not constitute a business. In such cases the acquirer shall identify and recognize the individual identifiable assets acquired (including those assets that meet the definition of, and recognition criteria for, intangible assets in IAS 38 Intangible Assets) and liabilities assumed. The cost of the group shall be allocated to the individual identifiable assets and liabilities on the basis of their relative fair values at the date of purchase. (IFRS 3.2(b)). This guidance presents the possibility that the initial value of acquired assets or liabilities is different from their fair values.

11.6. How can the guidance in IFRS 3 for determining if a transaction is a business combination be applied to a transaction that involves contracts in the scope of IFRS 17?

One can conclude from IFRS 3 that the necessary conditions for defining a transaction involving insurance contracts as business combinations are:

- the portfolio or group of contracts must constitute a business or be part of a business; and
- control over the portfolio must be obtained as a result of the transaction.

The addition of individual or multiple contracts to an entity's book of business in a single transaction may not be sufficient to qualify as a business combination. The act of issuing contracts is unlikely to be considered an acquisition or a business combination. For example, the issuance of several individual contracts to a single owner (e.g., as in the case of corporate-owned life insurance) or purchases of individual contracts in a secondary market (e.g., viatical settlements) would not be considered a business combination. A business combination may include the right to issue future contracts using the same distribution system associated with the purchased block. However, any values directly associated with such rights to issue contracts are not reflected in the liabilities or other values of acquired contracts but may be recognised as intangibles associated with the business combination, as discussed further below. Even without the transfer of the right to issue future contracts, the potential of the net cash flows associated with a portfolio of insurance contracts to generate profits may be sufficient for it to be deemed a business.

The transfer of a block of business from one entity to another may be considered a business combination if the acquirer obtains control of the associated contracts. An acquisition is distinct from a reinsurance transaction, other than novation or assumption reinsurance, since an acquisition transfers control over all aspects of contracts, whereas a reinsurer has at most limited control over the contracts reinsured. For example, an insurer may buy an individual line of business of a multi-line entity by buying certain assets, taking on its obligations through assumption reinsurance and taking control of the sellers' distribution system. The insurer in this example does not buy the shares of the seller, but nonetheless has acquired a business and would account for the transaction as a business combination.

11.7. What are the transition rules applying to business combinations or portfolio transfers that occur(ed) before the effective date of IFRS 17?

The general guidance in IFRS 17 for transition applies to contracts in the scope of IFRS 17 acquired in a business combinations or other transfer. As discussed above, the recognition date of the acquired contracts is the date of the business combination or of the transfer.
Hence the transition does not require the entity to go back to the origination of the contracts, but rather to the date the entity acquired them. There is no need to restate any existing goodwill balances.

There may be business combinations that occurred before the effective date of IFRS 3 or that were acquired before the first-time adoption of IFRS. The IFRSs allow some exceptions to the application to IFRS 3 to these transactions. For example, if a company deemed a business combination to be a merger under guidance in effect before IFRS 3, the initial value of the contracts acquired may not have been their fair value. The recognition date for these contracts is the acquisition date, nonetheless, not the original inception date. IFRS 17 nonetheless seems to require that the initial value for transition be the fair value at the acquisition date (see paragraph C4a) if the full retrospective or modified retrospective approach is used, or at the transition date if the fair-value approach is used. There may be less evidence about the fair value of contracts at the acquisition date for these transactions (those for which acquired contracts had not been measured at fair value on the acquisition date) than for contracts that the entity measured at fair value on the acquisition date. The actuary may find that the fair-value approach is more appropriate for these contracts.
Appendix to Chapter 11

This Appendix provides further information about IFRS 3

What is the guidance in IFRS 3 for recognizing and measuring identifiable assets acquired and liabilities assumed in a business combination?

IFRS 3 requires the identifiable assets acquired and liabilities assumed in a business combination to be measured at fair value at the acquisition date (IFRS 3.10 and 3.18). There is an emphasis on recognizing all identifiable assets acquired and liabilities assumed, reflecting the Board’s desire for entities to fully consider the difference between identifiable intangible assets and goodwill. The treatment of goodwill (see further below) is different from the treatment of intangible assets with definite lives and the allocation of the purchase price among these items affects the emergence of future profits.

To qualify for recognition, identifiable assets and liabilities acquired

- must meet the definition of assets or liabilities (IFRS3.11); and
- must be part of what the acquirer and the acquiree exchanged in the business combination rather than the result of a separate transaction (IFRS 3.12). Examples of separate transactions that do not constitute part of the business combination include settlement of pre-existing relationship between the acquirer and acquiree and remuneration to employees or former owners of the acquiree for future services.

Applying the recognition principles may result in recognition of assets or liabilities that the seller had not recognised in its FINANCIAL STATEMENTS. The application of the recognition and measurement concepts in IFRS 3 for intangible assets and other acquired liabilities is discussed below. The recognition and measurement of tangible invested assets, such as assets arising from ceded reinsurance invested assets, is not in the scope of this IAN. It is worth noting that there are some exceptions to the use of fair value measurement; for example, liabilities from retirement benefit plans are measured according to IFRS guidance for pension liabilities.

What are some examples of intangible assets arising from a business combination involving contracts in the scope of IFRS 17 and what are the accounting requirements?

Several potential intangible assets could arise from a business combination involving contracts issued by insurers. These include, but are not limited to:

- renewal periods for short-duration contracts
- distribution systems or relationships
- customer relationships
- service agreements
- brand names, trademarks, and copyrights
- proprietary software or technology
- licenses to transact insurance business
- product approvals and registrations
- value of liability guarantee

The following paragraphs provide descriptions of some of the more common intangible assets identified in combinations of insurance entities and some related considerations. The first step is, as already noted, to determine if the intangible asset can be recognized. If so, the entity determines the asset’s fair value and the appropriate technique for the amortization of the asset. Full development of common valuation and amortisation methods is beyond the scope of this IAN. While specific possible amortisation approaches are described for these assets, it should be kept in mind that IAS 38 provides that the amortisation period used should reflect the pattern in which an asset’s future economic benefits are expected to be consumed by the entity. If that pattern cannot be determined reliably, the straight-line method could be used. There is also the possibility that some intangible assets have indefinite lives, and hence the intangible asset would not be amortised, but rather tested for recoverability, referred to as testing for impairment. The actuary may wish to consult with accountants and other professionals, such as valuation experts, for assistance in determining which other potential intangible assets should be recognised, and how they should be measured and amortised and tested for impairment.

Value of renewal periods for short-duration contracts (sometimes also referred to as “customer lists” for short-duration contracts)

A common situation in non-life insurance is the establishment of an intangible asset related to the value of potential renewals of short-duration contracts. The fair value may be based on market pricing benchmarks if such transactions and related benchmarks are reasonably well established for the market in which the acquired business resides. Such benchmarks in at least some markets are based on a percentage of the premiums in-force or a percentage of annual premium writings. Absent such benchmarks, the fair value may be based on the expected future distributable earnings from renewal contracts, usually net of the cost of capital, discounted at a market discount rate commensurate with the risk of the cash flows. Among the methods for amortisation that have been used are:

1. in relation to expected distributable earnings used to derive the fair value estimate; and
2. based on expected premiums from future renewals.

Value of distribution systems/relationships

The value associated with a distribution system may be significant, especially for distribution arrangements involving contingent commissions, business processing or purchases of third-party intermediaries. Fair values of such systems can be derived from cash flow models and from valuation specialists. Two of the possible amortisation methods that have been used for future business are 1) in relation to expected distributable earnings, and 2) proportional to new business premiums.
Customer relationships and customer list – long duration contracts

Selling unrelated contracts to existing customers may provide the basis for an intangible asset or it may be included in goodwill, depending on the facts and circumstances. Care should be taken not to double count the value the asset related to a customer relationship and the value of a distribution system, if the considerations relate to the same future contracts and cash flows.

Service agreements

When a seller has entered into third-party contracts for certain services like claims administration, the acquirer considers whether an intangible asset might exist. There may be an intangible asset for the service component of investment or insurance contracts when this component is separated for recognition and measurement. Due consideration is given to whether the terms of such agreements are at, below or above current market rates. The intangible asset, if any, may relate to the amount in fees that represent an above-market margin.

Amortisation methods used for such intangibles include:

1. in relation to the net revenue (fees charged less costs to provide the service) earned for providing the service; and
2. on a straight-line basis over the contract period.

Brand names, trademarks, copyrights

The entity being acquired may have a legal right to certain items such as identifying names, slogans and logos that would qualify for separate recognition as intangible assets. Identifying the additional cash flows associated with such items may prove difficult. Amortisation would likely be based on the projected cash flows used to estimate the fair value. However, some legal rights may be renewable indefinitely leading to the conclusion that the intangible should not be amortised.

Proprietary software or technology

Some insurers have developed expert systems that can be separately recognised as having value. Such systems can include underwriting, distribution/cross selling, and investment management. Amortisation of such systems-related intangible assets may be a straight line over an assumed lifetime of the system.

Licenses to transact insurance business

IAS 38.88 requires entities to assess whether intangible assets have either a finite useful life or indefinite useful life. Licenses might be viewed as having an indefinite useful life, such that their value is not amortised over time (although they may be subject to an impairment test.). Their value might be derivable from market transactions for shell entities or from brokers in that market.

Product approvals or registrations
Product forms that have been approved for issue in certain jurisdictions can be determined to be intangible assets. The value could be viewed as the alternative cost to develop the same product and go through the approval process. Alternatively, the value could be viewed as something more if the product is in a niche market with limited access. Amortisation of the value could be based on the anticipated revenues expected from the sales of the new product.

**Value of Liability Guarantees**

Business combinations sometimes include guarantees regarding the claims liability run out, such as a guarantee to reimburse the acquirer for losses above a certain amount. The actuary will need to consider when such a guarantee is an identifiable asset that should be recognized at its fair value. When the guarantee is treated as a reinsurance asset and measured according to the entity’s current accounting policies the difference between the recorded asset and the fair value of the guarantee is reported as an intangible asset or liability. This treatment is consistent with the accounting for indemnification assets, as given in IFRS 3.28 and 3.57.

How does the entity account for goodwill or for a gain from a bargain purchase?

IFRS 3 requires recognition of goodwill as of the acquisition date. Goodwill is the excess of the consideration transferred over the net of the identifiable assets and liabilities acquired. Identifiable assets here include those intangible assets which have been recognized in connection with the acquisition. Goodwill implicitly includes intangible assets that do not satisfy the criteria for recognition. (IFRS 3.32)

Because consideration may include not only cash, but equities, future consideration or other types of compensation, the determination of the value of consideration can become complex. IFRS 3 provides some guidance on determining the value of consideration transferred. Of particular note is the fact that transaction costs, such as legal, advisory or accounting fees associated with the transaction are not part of the consideration.

Goodwill represents a payment made by the acquirer in anticipation of future economic benefits from assets that are not capable of being individually identified, recognised or reliably measured individually. The value of goodwill need not be justified, but is subject to tests of impairment. Goodwill is not amortised. Goodwill is to be measured subsequently at the amount recognised at the acquisition date less any accumulated impairment losses. The goodwill carrying amount must be tested for impairment in accordance with the requirements of IAS 36, Impairment of Assets (IFRS 3. B63).

The excess of the consideration transferred over the net of the identifiable assets and liabilities acquired may be negative. In this case, the acquirer reassesses the fair value of acquired assets and liabilities to be sure that all acquired assets and assumed liabilities have been identified, recognised and measured properly. If, after making adjustments for the reassessment, the excess remains negative, a bargain purchase is said to have occurred. There is no goodwill. The gain on the business combination is recognised in the acquirer’s profit and loss in the period in which the acquisition takes place (IFRS 3.33 – 3.36).

Can there be a deferred tax asset or liability as a result of a business combination or other transfer?
The guidance for deferred taxes is found in IAS 12 Income Taxes. The fair value of acquired assets and liabilities assumed in a business transaction may be different from the tax value of the respective assets or liabilities. Temporary differences arise from the business combination when the tax bases of the identifiable assets acquired and liabilities assumed are not affected by the business combination or are affected differently. For example, the initial value of insurance contracts acquired in a business combination is fair value, but the tax basis of the contracts may remain at the basis that it had to the seller. This difference is generally a taxable temporary difference which gives rise to a deferred tax asset or liability. (IAS 12.19) The deferred tax asset or liability is the amount of the difference multiplied by the tax rate that is expected to apply when the difference reverses. Hence the calculation may require a projection of the reversal of the difference, if it is necessary to reflect varying tax rates. There is however no discounting in the calculation of a deferred tax asset or liability.

The resulting deferred tax asset or liability affects goodwill (IAS 12.66). When a deferred tax asset or liability is recognized as a result of a difference between the fair value of an item and its tax value in a business combination, this difference is considered in the determination of the goodwill or the amount of the bargain purchase gain.

Note that the recognition of a deferred tax asset depends on the entity being able to assert that the asset is recoverable. A deferred tax asset is generally recognised for deductible temporary differences to the extent that it is probable that taxable profit will be available against which the deductible temporary difference can be utilized. The carrying amount of a deferred tax asset is reviewed at the end of each reporting period. The entity reduces the carrying amount of a deferred tax asset to the extent that it is no longer probable that sufficient taxable profit will be available to allow the benefit of part or all of that deferred tax asset to be utilized. Any such reduction can be reversed to the extent that it subsequently becomes probable that sufficient taxable profit will be available for the asset to be utilized.

What are the disclosure requirements related to business combinations?

Disclosure guidance for business combinations is found in IFRS 3, B64-B67. The disclosures include both qualitative and quantitative notes that “enable users of [the entity’s] financial statements to evaluate the nature and financial effects of the business combination”. The disclosures do not supplant disclosures required by IFRS 17. It may be necessary to make some of the disclosures for the acquired business separately. Although not explicitly stated in IFRS 17 or in IFRS 3, these disclosures may apply to transfers as well.
Chapter 12 – Transition

Before consulting this chapter, be sure to read the Introduction to this IAN, particularly the sections on References to IFRS 17, Materiality and Proportionality.
