

Credibility in Loss Development: Nonproportional Treaty Pricing Application

TO BE SUMMARIZED AT CLRS-Anaheim September 2018 LOB-13

CAS Seminar on Reinsurance; June 4-5 2018 David R. Clark

- 1) Review of Reinsurance Submission for Skipper Insurance Company
- 2) Credibility Theory for Loss Development
- 3) Final Pricing
 - a) Experience Rating
 - b) Credibility Blending Experience and Exposure Rates
 - c) Aggregate Distribution Creation
 - d) Calculating Final Price

Submission from Skipper Insurance Company

The benchmark patterns should vary for all relevant risk characteristics:

- Line of Business and Subline
- Coverage Trigger (claims-made vs. occurrence)
- Class of Business and Hazard (e.g., are pharmaceutical risks included?)
- Policy and Attachment Point distributions especially if excess business is included
 - Excess over company's own underlying ("supported") or others' ("unsupported")
- Claims Handling by insurance company or TPA
- Use of "signal" reserves

We can estimate the distribution of tail factors (LDF at age 96 months) as a finite mixture of three categories.

But this still means the tail factor is somewhere between 1.050 and 1.500.

Ideally, these Fast/Medium/Slow categories would correspond to specific risk characteristics.

Credibility Theory: Creating a Prior Distribution

In addition to the "client" data for Skipper Insurance Company, we have "industry" data showing the range of patterns collected by ISO.

For example:

10% = the average of the quickest10% of companies in the SOLMdatabase.

The "variance of hypothetical means" would be narrower than this range if we could control for the variance from individual companies.

Credibility Theory: Creating a Prior Distribution

The "penguin" from industry data (shown in **blue**) represents approximately a 90% confidence interval.

From a curve-fit to the client triangle, we can calculate comparable numbers (shown in **orange**).

For the 400K xs 100K layer, the client is much slower than the range of industry patterns.

Credibility Theory: Creating a Prior Distribution

The "penguin" from industry data (shown in **blue**) represents approximately a 90% confidence interval.

From a curve-fit to the client triangle, we can calculate comparable numbers (shown in **orange**).

For the 500K xs 500K layer, the client is much faster than the range of industry patterns.

Bayes' Theorem:

$$\pi(\theta|X) = \frac{f(X|\theta) \cdot \pi(\theta)}{\int f(X|\theta) \cdot \pi(\theta) \, d\theta}$$

This formula has three components:

 $\pi(\theta)$ A distribution representing "prior" knowledge of the parameters θ

 $f(X|\theta)$ A likelihood function representing the probability of observing the actual data X given a certain parameter set.

 $\pi(\theta|X)$ The "posterior" probability of the parameters, revised based on the data

When the prior distribution $\pi(\theta)$ and likelihood $f(X|\theta)$ are chosen such that the posterior distribution $\pi(\theta|X)$ has the same distribution form as the prior, then we have a *conjugate* relationship.

Common examples from the Exponential Family are:

 $\pi(\theta) \implies f(X|\theta)$ Gamma => Poisson

Beta => Binomial

For the loss development pattern problem, we need a multivariate conjugate relationship.

Dirichlet => Multinomial

Shi/Hartman "Credibility in Loss Reserving" (2014) https://www.casact.org/pubs/forum/14sumforumv2/Shi_Hartman.pdf Clark "Introduction to Bayesian Loss Development" (2016) http://www.casact.org/pubs/forum/16sforum/Clark.pdf

"Conjugate priors... have the desirable feature that prior information can be viewed as 'fictitious sample information' in that it is combined with the sample in exactly the same way that additional sample information would be combined.

"The only difference is that the prior information is 'observed' in the mind of the researcher, not in the real world."

- Bayesian Econometric Methods; Koop, Poirier & Tobias

For actuaries, our "prior" knowledge comes from:

- Understanding the loss-generating process
- Having reviewed many, many triangles in the past (this <u>should</u> take the form of "as if" observed data)

For our example, the creation of the credibility model follows these steps:

- Select Expected Fast/Medium/Slow patterns
- Create distribution around these patterns to mimic the range of the "penguins"
- Estimate the "process" variance/mean ratio for the excess layers
 - Dispersion parameter in ODP model
 - Variance/Mean from exposure rating $\approx E[X^2] / E[X]$

The benchmark factors are selected for three representative levels.

Because we know nothing about the risk characteristics for this client, our a priori weights for each benchmark curve are equal at 33.33%.

LDF		24.315	6.374	3.437	2.441	2.000	1.735	1.495	1.314

This procedure is repeated for each of the benchmark patterns.

The "slow" benchmark is closest to the empirical data so we will increase the probability of the client being in the "slow" development category.

Our a priori weights for the three benchmark curves were equal at 33.33%.

These weights are revised to reflect the fact that the client data most likely came from the "slow" curve. This revision of weights is a direct application of Bayes' Theorem. The revised weights can be the "prior" when we move to the 500x500 layer.

		Bayesian U	pdating of F	Probabilitie	S
	LogLikelihood	Difference in LL	Relative Likelihood	Original Weights	Revised Weights
	А	B=Max(A)-A	C=exp(B)	D	E=C*D/Avg(C)

Average	22.739	6.072	3.301	2.356	1.940	1.691	1.462	1.290	1.210	1.140

<u>A</u>	Posteriori Weights
Fast	0.18%
Medium	11.82%
Slow	88.00%

The same procedure is followed for the 500x500 layer.

Instead of the initial 33.33% weights for each benchmark, however, we can start with the result from the 400x100 layer. Because of the low credibility for the 500x500 layer, the final pattern is close to the "slow" benchmark.

All numbers for illustration only

Aggregate distribution model can be created using any one of our available tools (simulation, FFT, Panjer, etc.).

This distribution allows for the evaluation of loss sensitive treaty features:

- Annual Aggregate Deductible
- No Claim Bonus

The selection of expected losses to the 500K xs 500K layer is the starting point for our pricing.

- Additional Costs for ECO/XPL?
- Aggregate Distribution for loss-sensitive features
- Investment Income and NPV calculation
- Profit and Expense loads

Thank You
